Some improvements could be made to the Operator's Manual. Additional technical information, and *at least* a schematic, would be an asset.

Summary Evaluation

As a multi-function dedicated communications terminal, the 9000E meets all of the requirements. It is mechanically and electrically well-constructed and has a pleasing appearance. All controls are ergonomically correct, and the keyboard has excellent tactile response.

Although it was not possible to evaluate filtering bandwidths without laboratory specifications, the filtering appeared adequate under all situations. The crystal-controlled AFSK signal appeared to be well within tolerance, but no specification was given for this either.

From an operation viewpoint—and this could be the proof of the pudding — the 9000E came up to all expectations and beyond. Every function operated as specified and operating ease was exemplary.

This is an excellent communications terminal; beginners, experienced operators, and anyone in between will feel very comfortable with it. I can recommend it highly for anyone looking for an outstanding piece of equipment, one which not only allows full on-the-air capabilities, but also is excellent for line communications and computer and word-processing operations.

For more information on the Theta 9000E communications terminal, contact the *R. L. Drake Company, 540 Richard Street, Miamisburg OH 45342.*

HEATHKIT ULTRAPRO CW KEYBOARD

Have you ever felt that your CW sending could sound better? Have you felt perhaps, too, that to improve from where you are would take more time and effort than you would like to invest? You need to consider the new Heathkit Ultrapro CW keyboard (HD-8999).

Hams more familiar with a Stillson wrench than a keyboard soon become proficient at keyboard sending, with the promise of perfection which a keyboard offers. If you're ahead of the Stillson wrench group and know where the keys are on a typewriter or computer, with the Ultrapro, you too can be on your way to a dramatic improvement in your keying.

Buffer Memory

The Ultrapro is a compact gem of a keyboard that tends to turn the operator into the pro that the name implies. The crucial element in the keyboard for accomplishing this perfection is its buffer memory. The Ultrapro has a 64-character buffer, which is ample for high-speed sending.

Given my typing ability, a buffer of more than five to ten characters is gilding the lily at 45 to 50 wpm. What the buffer does is accumulate any characters I can type into it faster than I have set the keyboard to send. This affects my sending in three ways.

First, Ultrapro will stack those characters next to each other for perfect spacing of letters and, with the stroke of the space bar, the spacing of words. This action eliminates the little imperfections in timing that occur even with rhythmic typing on a keyboard without a buffer. If I have a momentary distraction, again, it won't show up in the middle of a word or sentence as a gap. Such gaps can be even more distracting to the person attempting to copy high-speed code.

A second effect is the minimization of keying errors. If I realize I have punched the wrong key, I can simply backspace one space ("delete" on the Ultrapro) and retype. The backspace both erases the error and resets the position in the word for the right letter. If my error is three letters back in the word, I backspace three and retype all three. Because I'm obliged to retype anything following the errors, I don't have to count forward to be able to start where I left off.

If I'm not sure of the entire word, or of even two or three words, I can shift/delete and, with each punch of delete, the last word or part of a word will drop out, leaving the space after the remaining word intact. Then, I merely continue to add to the buffer by typing in the correct words.

The third thing the buffer gives me is time to think of what I'm going to send next without having to throw in some potentially annoying (punctuation) dashes. The overall effect of the buffer, then, is to smooth the test into what we used to call tape-machine perfection.

In addition to the rapid correcting which the buffer memory affords, the two-key roll-over feature also facilitates fast typing. Simply stated, if I punch a second key before I let up on the previous one, the letters are entered in order as long as I let up on the first key before the second. Without this feature, neither might be entered or, possibly, only the first letter.

Commands also can be stored in the buffer so that, while typing ahead, I can tell the board to speed up ten words a minute right after I say I will. Weight and spacing changes may be accomplished in the same manner. The board will then type on at the previous setting until the buffer empties to the command that I gave. This can be a slight disadvantage if I decide that I want the change right away during a transmission. If I have any text in the buffer, I must wait until that text is transmitted before my command is fulfilled, unless I want to dump the buffer contents with the stop key, make a command, then retype what was dumped. This shows up as a short hesitation in my transmission

Hold Function

A distinctively larger hold key freezes the emptying of the buffer into the transmitter. This feature is good for a couple of reasons. If I'm operating QSK and think I hear a breaker, an interfering signal, or the person I'm talking with, I punch hold. If it's nothing that requires a response, I punch the hold key again and the buffer continues to transmit from where it left off. If a response is required, I punch another larger command key, the stop key. Then I can begin filling the buffer memory with my response if the signal from the other station continues. If the transmission is short, or stops, I punch the hold key a second time to re-enable the transmission of whatever I now type into the buffer.

Hold is also useful when the other station is about to turn it back to me. I punch hold. This condition is displayed on the LED digit display until I punch hold a second time. I then insert perhaps the other station's call and add my ID from the 495-character programmable memory. I'll write more about that later. Then I can type "R R" and start typing my reply into the buffer. As quickly as the other person signs "K", I hit hold the second time and continue to type into the buffer while it starts transmitting for me. This feature gives me more of that time we were talking about to think, type, make errors, and correct them.

Programmable Memory

The second type of memory in this board is intended to be filled with parts of transmissions that are recurrent in QSOs. There is available in this memory 496 characters worth of space. This memory is addressable at ten points by punching shift and then one of the digits from zero through nine. I don't have to cramp each message into a space 49.5 characters in length, either. That's because this memory has what is called soft partitioning, which enables me to mix long and short messages up to the full utilization of character spaces. I don't even have to enter them in numerical order.

Filling or changing any particular segment is easy, too. I punch set, the number of the compartment, and load. When I finish loading, I punch stop. This stops further entry into the programmable memory and enables the board for immediate sending. To delete a compartment to make more space available, I hit set, the number of the memory I'm sacrificing, load, and then stop. Each of these messages can be protected from the above by a protect command with the number of the compartment.

Inserting the command into the buffer memory to read one of these segments in the programmable memory takes up only one character of space in the buffer. This maximizes its available space. On the other hand, commanding a speed, weight, or spacing change will take up three or four spaces in the buffer.

Contesting

For the contester, aside from the board's handy programmable memory described above, it will send serial numbers - one each time you command its transmission. If you need to repeat a serial number in a QSO without the number's increasing, you command the previous serial number as many times as you need. While you are using this feature, the serial number is displayed continuously on the LED digit display instead of the transmitting speed, which is usually displayed.

The LED digit display is effective in providing the status information the operator needs. A punch of the weight or spacing keys results in a brief display of the parameter, then a return to the wpm value. Loading any of the programmable memories results in the display of a number anywhere from 495 to zero, depending on the remaining space available in these memories. Eight colored bars, five green, two yellow, and one red, denote the consumption of spaces in the 64-character buffer memory, eight letters at a time. During the time that the buffer memory is referring to one of the programmable memories doing a transmission, a small green dot on the LED display signals this to the operator.

An interesting feature of the circuit is its ability to evaluate itself. A flick of the reset switch on the back of the board runs the microprocessor and integrated-circuit diagnostic tests. If all is well, the buffer-status bars will light briefly, and the speed will set and indicate at 20 wpm on the LED digit display. If one of the ICs or the microprocessor is faulty, the circuit component number (e.g., U-2) will be displayed. This feature could take a lot of guesswork out of troubleshooting the keyboard.

Memory of the sending parameters as well as of the programmed material is preserved with minimal current from a battery if the unit is disconnected from its power source. The unit will operate from a range of 7.5 to 11 V ac or 11 to 16 V dc of either polarity.

Code Practice

The code-practice mode offers several useful features to those so inclined. In addition to the usual, some of these features are: (1) selection of type or types of characters on which you wish to concentrate; (2) selection of desired speed, spacing, and weight; and (3) selection of copy mode, using which you must press the correct key after hearing the character before the board will give you the next one. The code-practice mode utilizes random-length and five-character-length groups, not words. My feeling is that this mode might be useful to the early learners of CW to whom the owner of the keyboard might like to be of assistance. I can't recommend staying long with copying random groups to the person interested in learning code at higher speeds.

The Ultrapro keyboard is light (shipping weight 7 lbs.) and stable on a desktop or held on the lap. The keytops are slightly sculpted and the action is without wobble, giving touch and sound feedback that is not obtrusive. A shift/tone command will add level-adjustable sidetone. The key spacing approximates that of my electric typewriter and feels optimal to me. The feel of the board is one of an electromechanical device designed for long, trouble-free service.

Conclusion

As if all the foregoing features weren't enough to commend this new Heathkit, the price for the kit seems quite reasonable: $249.95. And if those features don't quite qualify you sending for Ultrapro status, sprinkle it with the exclamation point, parentheses, semicolon, and colon — these should heighten the color of your QSOs (I've been too fainthearted to use them)! I recommend this kit to anyone who is interested in making a significant improvement in his sending, whether he or she communicates best at 5 wpm, 99 wpm, or somewhere in between.

EGBERT II RTTY PROGRAM

Most of the gear I review comes carefully packed in one or more large cardboard cartons. The Egbert II RTTY program was an exception. It arrived in a plain, large-size manila envelope. But Egbert II's inauspicious size and packing material are certainly made up for by its features. Simply put, Egbert II offers all that you need to turn your Apple computer into a RTTY terminal. (Well, not quite all... you will need some cables to go between the rig and computer, but that's it.) No terminal unit, no interface card, no extra demodulator circuits. It is all right there on one floppy diskette.

To use the Egbert package, a 48K Apple II, II+, or IIE with one disk drive and Applesoft Basic is required. A printer is optional. If you are a Franklin Ace 100 or Ace 1000 owner, then you must provide some sort of modulator and demodulator since the Egbert program typically utilizes the Apple's cassette interface not found on Franklin computers. Also available under the Egbert name is a CW transmit-receive program for the Apple and a program for transferring Applesoft, Binary, and Integer disk files. This review deals only with the RTTY portion of the package.

The software comes on a single 13-sector copy-protected disk with the user's callsign already embedded. Getting on the air is very simple. First one must create a 16-sector message disk and hook up cables to the receiver audio output, transmitter mike input, and, if desired, the push-to-talk line. The only interface circuitry that may be needed is a 10k-Ohm pot for adjusting the mike drive level and a transistor switch to work between the Apple's TTL level T/R and your rig's push-to-talk line.

It takes about 30 seconds to load the software and insert a message disk. Each initialization step is menu-driven and can be passed through quickly to reach the default mode of 60-wpm RTTY with a standard 170-Hz shift. Or you can enter in your own parameters: Baudot at 60, 67, 75, and 100 wpm, ASCII at 110 baud, any desired mark-space combination, and tone reversal to invert the mark and space frequencies.

The final step before operation is setting the receive frequency. High-resolution graphics are used to display the relationship between the software-driven filtering and the actual mark-space frequencies. You may tune in a signal by adjusting the receiver until the display lines up or by shifting the computer filtering via one of the Apple's arrow keys. With tuning complete, you press RETURN and start receiving. During reception, the graphics are replaced by two flashing stars, allowing you to make minor adjustments in the tuning.

Egbert II offers split-screen operation; received data is displayed on the upper portion of the screen while the bottom three lines are devoted to a type-ahead buffer for your response. If the op on the other end is long-winded, then you might want to use the receive buffer. This saves the received text to memory while it is being displayed. A separate set of commands saves the buffer to disk. Viewing the data is done through the Print Buffer option and can be done via the screen or a printer. Another option is the real-time print option where incoming data is both displayed on the screen and printed out. Although I didn't test this feature, the printer program can accommodate a Votrax speech synthesizer so that words are spoken as they are received.

Transmit features include the type-ahead buffer, a quick break that allows your reply without disturbing the transmit buffer, and automatic CW ID at the end of each transmission. If you are using a message disk, then it will take only two keystrokes to transmit any one of nine canned messages. Each message has an independent length, with a total of 4800 characters allowed for the group. Another help is the inverse display for every 65th character typed. This is handy when working a station with a mechanical teletype machine, indicating that it is time to insert a carriage return.

In addition to normal transmit and receive operation, the Egbert II program offers limited mailbox capability. The computer operates unattended, saving incoming messages to memory and then to disk when the memory is filled. Two options are available: You may store all incoming messages on a particular frequency or just those that are preceded by a special recognition code. Unlike some of the more sophisticated mailbox systems, the Egbert II program is limited to receive-only operation.

The hardware-free approach of Egbert II warrants a closer look. At the heart of the system, you'll find the Apple's seldom-used cassette I/O and some unique software. The cassette input circuitry is merely a level detector, converting the incoming sine wave into a square wave. The Egbert II software does the rest of the job, measuring the frequency of the signal and determining if it is a mark or space.

This approach is not without drawbacks. Signals must be strong and in the clear. Remember, there is no filter to prevent a signal adjacent to the one you want from being read by the Apple. In practice, I found the Egbert II hardwareless design to work quite well and was able to copy the majority of the stations I heard. Judicious use of the rig's (a TS-830) filters was a great help. If your receiver is lacking in this department, then I recommend using a tunable audio filter between it and the Apple.

For serious HF operation, you may want to use a terminal unit. The Egbert program accommodates this by using the Apple game port as an alternative input. The TU must have TTL-level outputs for the received mark and space signals and be compatible with a TTL signal for transmit.

The high-resolution tuning display is a nice touch, but I usually dispensed with it and relied on the simpler two-star tuning aid. With a bit of practice, I was able to tune in a signal in just a few seconds. The fancy tuning display needn't be forgotten, though; the instruction manual suggests that it can also be used as a graphical frequency counter.

My only complaints center on the Egbert II transmit operation. The type-ahead buffer has a backspace feature that is handy for making corrections, but unfortunately there is no cursor to indicate where a correction will take place, making it easy to get lost. A second drawback is the way in which the type-ahead buffer disappears every time you switch to transmit, even if it is only for a quick break. The information is still in memory ready for the next transmission, but there is no way to find what it is without going back to transmit.

A seasoned RTTY operator may find the Egbert II software to be too simple for day-to-day use. However, I feel that the lack of bells and whistles makes the program ideal for beginners. All the necessary commands are displayed on the screen and you can become an expert in a half hour or less, including the time it takes to interface your Apple to a rig. Sure, the software-driven terminal unit won't equal the performance of a dedicated circuit, but you just might be surprised at how

well it does work. One thing's certain: Hams that own an Apple won't find a more painless or less expensive way to try their hand at RTTY.

The RTTY portion of this program is available for $39.95. For more information, *contact the W. H. Nail Co., 275 Lodgeview Drive, Oroville CA 95965.* Reader Service number 486.

RTTY89 RADIOTELETYPE COMMUNICATIONS PROCESSOR FROM COMMSOFT

As digital communications slowly but surely revolutionizes amateur radio, many firms have taken a stab at producing computerized RTTY programs. Few companies have accomplished this task more skillfully than Commsoft, makers of RTTY89, a radioteletype program for the Heath H89 All-in-One microcomputer. RTTY89 was written by Howard L. Nurse W6LLO and is designed to make maximum use of the special function keys and 80-column video display capabilities of the H89. This combination of computer and software, along with the best instruction manual in the business, comprises a truly outstanding RTTY system.

Specifications

In the simplest terms, an H89 computer running the RTTY89 program is merely a solid-state substitute for a mechanical teleprinter. But that's only the tip of the iceberg. Unlike any mechanical unit I know of, RTTY89 allows you to switch between any of four Baudot and three ASCII speeds at the push of a button.

In common with all of the better computer RTTY programs, RTTY89 features a split-screen display. The upper portion of the video screen shows the incoming message, while you simultaneously use the lower portion to compose your response. Your message is stored in what Commsoft calls the "pretype buffer" until you press two keys to begin transmitting. Both incoming and outgoing data can be automatically sent to a printer or floppy disk for a permanent record of your RTTY contacts.

A number of permanent messages are stored in the program and may be called up for transmission at any time. These include a "CQ" with your call inserted in the appropriate spot; a line of "RYRYRY..." or its ASCII equivalent, "U*U*U*...", for testing and tuning; a special preamble for the start of your transmission featuring a CW ID, time, and date; and a similar closing for the end of your messages. In addition, you can create three short, custom messages of up to 70 characters each. Both the permanent and user-created messages may be called up for transmission with a single keystroke. Longer messages of your own design, such as brag tapes, can be created at your leisure using a word processor and stored on a floppy disk. Then they can be recalled from disk during RTTY operation and inserted into your outgoing message.

Among the other outstanding features of RTTY89: no loss of received information when loading text from disk; the ability to send messages with justified right margins and distinctly customized left margins; the option to repeat the previous transmission; editing of the last letter, word, or line in the pretype buffer; automatic activation of transmitter push-to-talk when sending; automatic CW ID at an interval you select; and word wrap-around at the end of a line (a word is never split in two).

The Hookup

The RTTY89 program uses the RS-232C serial input/output port of the H89 to communicate with the outside world. In this case, the "outside world" is a RTTY terminal unit (TU) connected to an amateur transceiver. A cable is run between the RS-232C connector on the rear of the computer and the TU. The TU, in turn, is connected to the mike socket and the headphone jack of the transceiver.

In my shack, the terminal unit is the popular Flesher TU-170. Like a number of other TUs, the 170 does not have an RS-232C interface as standard equipment. Fortunately, the Commsoft instruction manual contains a schematic for a simple RS-232C circuit which can be built from Radio Shack parts and added to an existing TU. I did this with my TU-170, and it worked perfectly. If your TU has RS-232C capability, so much the better.

On the Air

Once the wires are connected and RTTY89 is initialized with the time of day, your callsign, and other pertinent information, it's time to tune in some RTTY. In my case, I simply tuned the rig to 40 meters and Bingo! Beautiful RTTY printouts began marching across the video display of my H89 computer. I was in business!

After assuring myself that the receive portion of the system was working properly, it was time to try transmitting. After all, RTTY reception is only as good as your receiver and TU; it's on transmit that RTTY89 would really shine.

And shine it did. I found a WA4 station calling CQ and carefully tuned him in. As he called, I composed a response on the lower portion of the split screen. Hesitantly at first, then with more confidence, I built up my message in the pretype buffer. First, I hit the computer's Blue function key to enter the preamble (CW ID, RTTY ID, time, date), then a control-V let me enter his callsign, along with my call, name, and QTH. Pressing the Red function key twice repeated this information two more times. The White key entered a closing, with a CW ID. I then entered control-R to put the system back into receive after the transmission.

Remember, all of this was done while the WA4 was sending his CQ. RTTY89 stored my whole response in its pretype buffer while never missing a bit of the WA4's message. Soon, the CQer completed his call. To send my entire response, I merely pressed control-T, then sat back to watch my message being sent out by the computer, complete with CW IDs in the right places.

This business of function keys and control keys sounds pretty complex, but it's amazingly straightforward in practice. For starters, Commsoft's manual does a terrific job of explaining each command. Also, the most often used commands are mostly single keystrokes or easily remembered (control-T for transmit, control-R for receive). Finally, RTTY89 includes a compact prompt card to be posted at the operating position. The card neatly summarizes all 46 (!) commands and gives brief examples of typical operating procedures—extremely helpful.

Summary

I've had the opportunity to use seven different computer RTTY systems, and in one way or another, many of them have proven awkward to use. Some are poorly conceived from the start. Others are badly documented, so that only a RTTY expert can puzzle out how to make them work. Some otherwise fine products have been ruined by poor instructions.

RTTY89 stands out because it works smoothly and efficiently with a minimum of fuss. It is superbly designed and documented and more easily understood than systems with half the number of commands. The ease with which complex messages can be built up with a minimum of keystrokes is remarkable and allows even slow typists like me to have great fun on RTTY. The designers of programs for today's low-cost computers should take a lesson from RTTY89. It's too bad there aren't more H89s around.

The Commsoft RTTY89 program sells for $34.95 from *Commsoft, 665 Maybell Avenue, Palo Alto CA 94306.* Reader Service number 488.

SPRATLY ISLANDS— DX DISASTER

The widely-scattered reefs and rocks of the Spratly Island group in the South China Sea have long been one of the oddballs in the DXCC "Countries" list. Claimed by every country in the region, and (until recently) uninhabited, the 100 or so tiny islands offer a severe challenge to the determined DXpeditioner. And that challenge proved too much for two German amateurs who died in an April, 1983, attempt to operate from Spratly.

What *really* happened to the group led by Baldur Drobnica DJ6SI? Baldur has put the rumors to rest with a cassette tape, relayed through Ralph Hirsch K1RH, and translated with the assistance of the language department of Southern Connecticut State University.

But first let's review the amateur radio history of the Spratly group. The infamous Don Miller W9WNV claims the first operation from Spratly in the mid-60s. Don used the call 1S9NWN, the first use of a prefix beginning with 1, which is not issued by the International Telecommunications Union (ITU). Don claimed operation from the largest island of the group, Spratly.

Photo A. Phil Weaver VS6CT kept the amateur radio world informed of the progress of the search for Baldur's ill-fated Spratly DXpedition. Phil provided additional details at the Visalia International DX Convention this past spring.

The next Spratly operation was engineered by Don Reihbott K7ZZ, from Vietnam, in 1973. Don commandeered W4EBG, N5TP, and others to mount a major DXpedition to Spratly Island, well documented by Don's ever-present Super-8 movie camera.

Spratly worked its way up the Most Wanted list until 1979, when K1MM and K4SMX boarded VK2BJL's yacht for another attempt at the island group. Their goal was Amboyna Cay (about 100 miles southeast of Spratly Island), as Spratly was firmly in the grasp of trigger-happy Vietcong. Amboyna Cay was also inhabited by unfriendly natives, and the group retired abruptly when gunfire erupted from Amboyna. They moved to a tiny sandbar, Barque Canada Reef, a few miles to the northwest. Several less-courageous (more reasonable?) members of the trip stayed in Brunei while the three intrepid DXpeditioners operated from an unadministered island too close to Malaysia to count as a separate DX country under DXCC rules.

Many other DXpeditioners who watched Spratly move up the Most Wanted list investigated the possibility of another trip to the region, but maritime warnings, the advice of the US Department of State, and the experience of the last DXpedition to the area discouraged most amateurs.

Which brings us to DJ6SI's attempt. Forty-eight-year-old Baldur Drobnica originally aimed for a DXpedition to St. Peter and Paul Rocks (PY0) off the coast of Brazil, but a recent DXpedition had knocked PY0 out of the top 25 of the Most Wanted list. Of the other DXCC countries on that top 25 list, most had political rather than logistical reasons for lack of amateur radio activity (see this column, December, 1982). Heard Island was well covered (see this column, August, 1983), and the season was wrong for an assault on Bouvet, 3Y1. So Baldur narrowed his choice to Clipperton (FO0) and Spratly. Clipperton required a long trip through Tahiti, as well as special permission

since a previous DXpedition had to be rescued from their Pacific reef. So Baldur chose Spratly.

Baldur first contacted a fellow West German in Brunei to locate a boat to sail to one of the Spratly islands. Despite the close proximity to Spratly (or perhaps because of it?), he was unable to locate a boat and crew for the DXpedition. So Baldur turned to Singapore, a few hundred miles further away. An ad in a sailing magazine led to negotiations with the skipper of *Sidharta*, a 50-foot catamaran, and the trip to Spratly was on!

Warren Gough 9V1VC provided invaluable local assistance, especially in locating the generators, fuel, etc., needed for the DXpedition. This help reduced the time the West German DXpeditioners had to spend in Singapore to a mere two days. On March 31, four amateurs left Cologne for Singapore. After locating a couple of 5.5-meter aluminum poles for antenna masts, the amateurs and crew set sail on April 3 from Singapore harbor.

On board the yacht were Baldur, Norbert Willand DF6FK, Gero Band DJ3NG, and Dietheim Mueller DJ4EI, along with the captain, Peter Marx, and his wife Jenny Toh Swee Neo. After dodging shoals leaving Singapore harbor, the group headed for the Natuna Islands, halfway to Spratly. Their 5-knot speed was putting the group behind schedule, and they still wanted to operate for five full days from Spratly, so they changed their plans to end their sail at Brunei.

As they reached the open water past Natuna, heavy seas forced a slight change in course from 65° to 75°, so they sailed into the Spratly group somewhat east of their intended course toward Barque Canada Reef. They spotted Amboyna Cay, which was covered with military structures and other buildings, but no people, as far as they could tell. But as they changed their course from Amboyna to Barque Canada Reef, about 30-40 kms away, gunfire erupted from Amboyna.

The yacht was about a mile or so from Amboyna, and clearly sailing *away*. Pat N0ZO/DU2 was in radio contact with the yacht, and other stations were undoubtably listening in to the progress of the DXpedition. The first round from Amboyna fell short—the proverbial "warning shot"? The *Sidharta* sailed as fast as possible away from Amboyna, but the next shot hit the yacht, wounding captain Peter Marx in the chest. The group was fighting to get out of range of the gunfire when a third round hit 120 liters of gasoline stored on board. Dietheim Mueller DJ4EI, who was standing next to the gasoline when it exploded, was never seen again. He couldn't swim.

Photo B. Dr. San Hutson K5YY was recently elected to the CQ DX Hall of Fame. Congratulations, San!

The rest of the group ducked down the hatchway to escape the gunfire, with the FT7 still on the air. "Fire on board, Fire on board!" was the last radio communication heard from the now burning vessel. The group, now certain they would have to abandon their craft, escaped the cabin through the skylight. They grabbed a 70-liter fresh water tank and lashed empty fuel barrels to it to keep it afloat, but their dinghy was hanging from the stern of their yacht, which was engulfed in flames.

When the propane bottles for cooking exploded, the group abandoned the *Sidharta*. Jenny swam around the burning yacht to rescue their dinghy, which fortunately had been freed from the yacht as its lines burned through. The shelling continued as the group piled into the tiny 14-foot boat, and one round opened a hole in the dinghy. They used what little clothing they had brought with them to block the inflow of water, but they had to bail continuously thereafter.

Meanwhile, they continued to call for DJ4EI, but they saw no trace of Mueller after the third shell. Their careful salvage of the fresh water tank was for naught; it drifted out of reach. Water in the other tank was contaminated with seawater and undrinkable. The gunfire continued as the dinghy drifted slowly away from Amboyna under the pressure of southwest winds. Fortunately, the high seas screened them from most of the gunfire, but the group huddled in the bottom of the little boat as shells rained down around them.

At first, the spirits of the five remaining members of the DXpedition were good, despite the ordeal of losing their good friend Mueller, the yacht, and radio gear, not to mention the end of their DXpedition plans. They knew they had been in radio contact up to the minute they abandoned ship, with their location well known. It wouldn't be long, they reasoned, before a plane would drop a well-equipped life raft and supplies, followed by eventual rescue.

But days began to pass without a plane in sight. Baldur inventoried their supplies in the dinghy: their bathing suits, a couple of T-shirts, Baldur's parka, a woven basket, a glass jar, a screwdriver, and a couple of empty fuel cans. They rigged the empty cans as sea anchors to help stabilize the tiny craft, and used the screwdriver to remove a stainless-steel plate at the stern of the boat, where the outboard motor would be attached. They intended to use the shiny plate as a mirror to attract the attention of rescue craft.

Peter Marx, an able seaman with a German license, provided invaluable advice on survival in the open boat. Without food or fresh water, they could not exert themselves in any way, so they dismissed the idea of rowing. As the sun beat down and there still were no rescue planes, the survivors fashioned a rough tent-like cover from Baldur's parka and Jenny's sarong, but it provided little shelter. Baldur tried to catch fish with the woven basket, but his only luck was with tiny, finger-sized minnows. The still-living fish were difficult to swallow without water, and most of the survivors gave them up even before the basket drifted away.

Baldur, now deeply concerned that they would not be rescued, scratched an account of what had happened on the back of the steel plate, using the screwdriver. Even if they all perished, the world would know what had taken place. Days continued to pass, with a NNE wind blowing them slowly toward shipping lanes to the south of the Spratly group. On the sixth or seventh night, a brightly-lit ship passed a short distance away, but they had no way to attract attention. The shiny metal plate was useless at night. As they drifted through the more heavily travelled shipping lanes, they saw more ships, but only at night.

Meanwhile, Gero Band DJ3NG grew steadily weaker and began to hallucinate that they had been rescued. He drank some seawater under the delusion that it was fresh, and this may have led to his death a short time later. At about 1:00 pm on April 18, Gero died, and was buried at sea, just 30 hours before the survivors were finally pulled from the sea.

Baldur, too, began to hallucinate, dreaming that a voice told him he would be rescued on the tenth day. As that tenth day in the dinghy without food or water ebbed into sunset, a large Japanese ship, the *Linden*, passed close by. The survivors couldn't yell with their dry throats, and the *Linden* sailed on by. But then Jenny noticed the ship had changed course, steaming around in a circle, back toward their dinghy! Rescue was finally at hand, after 243 hours!

The *Linden* pulled alongside, and Baldur scrambled aboard, the only survivor with the strength to do so unassisted. The Japanese crew of the Panama-registered *Linden* then took careful care of the weakened DXpeditioners. Small amounts of warm fresh water first, and then long-awaited showers began to restore their strength. Their medical problems were mainly sunburn, especially severe in Willand's case. The Japanese treated burn blisters on their hands, feet, and faces, and soothed the sores caused by sitting in wet bathing suits on rough wood for ten days. Strained rice soup and clean sheets completed their first evening after rescue; Baldur thought they were in heaven as he slipped into bed!

End of Part 1. Coming next month: The aftermath. Unanswered questions abound, and the last chapter of the Spratly saga has not been written. Copyright 1983, by Baldur Drobnica DJ6SI.

DR. DIGITAL

Robert Swirsky AF2M
412 Arbuckle Avenue
Cedarhurst NY 11516

The most important development in the history of amateur radio came on October 28, 1982, and, unfortunately, it went by unnoticed. What was this event? The legalization of *any* digital (i.e., computer) code on the amateur frequencies above 50 MHz (except for the CW-only portions of 6 and 2). As long as the codes are not intended to make one's communications secret and a detailed record of the format of the digital codes is maintained, it is legal. For the complete rules, see part 97.7.

Why is this so important? Well, for one thing, hams are now free to *experiment*, something that was severely restricted under the old rules. In the past, it has been amateurs who pioneered various methods of communication; now hams can continue being pioneers.

It is impossible to go very far these days without encountering a microprocessor. These devices, in some form, can be found in everything from automobiles to watches. Amateur radio, being no different from anything else, also has been computerized. Practically all the new transceivers are microprocessor-controlled. Many hams have taken up the study and use of computers as a hobby. It is only natural that a person interested in electronics would want to learn about computers.

The typical ham's use of a computer, however, has been far from revolutionary. Sure, many hams have replaced their noisy Model 19 Teletype* machines with the silent CRT, but that really isn't enough. Computers can do so much more than simply send RTTY or CW, and one needn't spend a fortune to use a computer in other applications.

Computers can be used to assist with practically every mode of communication. Slow-scan television and facsimile can easily be enhanced using digital (computerized) techniques. Even voice communications can be digitized. Using a technique called pulse-width modulation sound input can be digitized (converted from analog to a digital representation) and sent as digital data. Various techniques for compressing the data exist and on the receiving end, the voice can be recreated using a digital-to-analog converter. Recent advances in integrated circuit technology make experimenting along these lines well within the reach of any dedicated amateur.

The purpose of this column is to show other uses for a computer besides RTTY. Sure, RTTY is wonderful with a computer but computers can do so much more. I will try to provide examples for all the popular microcomputers so that no one will feel left out. Particular emphasis will be on the lower-cost microcomputers. Where possible, I will show how some fancy software can take the place of elaborate hardware. By doing this, I hope to provide somethin

for everyone, including those hams who don't have the kilobucks to spend!

Hams must get their computers talking to each other. Murray (Baudot) code at 60 wpm simply is not the most efficient way for two computers to communicate. What is needed is a faster, more reliable method with error-correction and error-detection. Not only text can be sent, but programs, graphics, and even data representing music and sound!

Before hams can start getting their computers on the air, some standards must be established. In the coming months, I will set forth my own ideas regarding such standards. Now you may be saying to yourself, "Who is this AF2M to go around setting standards?" Well, why not? I am not affiliated with any ham radio or computer manufacturing company, so I will be completely objective. My suggestions for a digital communications standard are:

1) Low cost. No expensive or unusual hardware should be required.

2) Easy implementation on any computer. Individuals with a Timex 1000 and an IBM PC should be able to communicate.

3) Software over hardware. I favor the software solution to an interfacing problem. In my opinion, it is much easier to tinker with op codes than with chips.

4) Reliability. There should be error detection and correction.

I would like to see computer graphics exchanged over the air, even between different computer systems. There are some graphics standards around now; it is time to start implementing them!

I think I'll get off the soapbox now and start in with the fun stuff.

CASSETTE-PORT QSO

The new FCC rules now allow for cassette-port QSOs. If you are on VHF, you can exchange programs or data over the air with the cassette I/O. Of course, it is only possible to exchange data with someone who has the same type of computer (or an emulator). It takes a little fiddling with the volume levels, but it is possible. Better results can be obtained if the audio is regenerated before it is sent to the computer. Regeneration is almost always necessary with the VIC-20 and VIC-64 computers. However, fairly good results can be obtained with the Apple, TRS-80 I or III, and the Timex/Sinclair computer with no additional circuitry. Once the proper volume levels are established, the data transfers can be just as reliable as cassette tapes are.

If you have an Apple, TRS-80, or Timex/

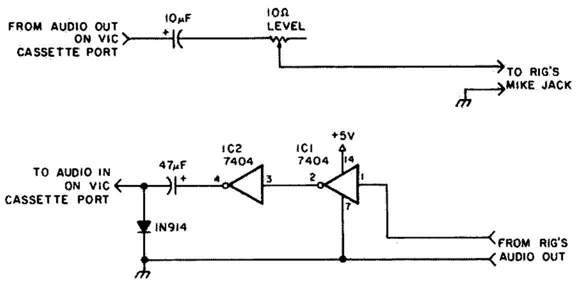

Fig. 1. VIC-20 cassette-port-to-ham-rig interface.

Sinclair, simply connect the cassette output to the microphone input of the rig and the audio output of the rig into the computer. Make sure to use shielded cable to prevent the rf from the computer from interfering with the radio. Fortunately, on the VHF and UHF frequencies where this type of operation is legal, computer RFI becomes less of a problem. Carefully monitor your transmitter output and adjust the microphone gain for a normal amount of deviation—about the same as you would expect from a voice signal. To set the proper receive level, use the same procedure as you would to set the level of the cassette recorder. It might take a little experimentation, but once the proper settings are found, you won't have to worry about them again.

With a Commodore VIC computer, try the circuit shown in Fig. 1. The integrated circuit is just a 7404 hex inverter to ensure that a perfect square wave goes into the computer. To feed audio into the rig, the 10-µF capacitor improves the audio quality. Fig. 2 shows the pinout of the VIC-20 cassette port. Note that you can power the interface circuit from pin B-2. It is important that you ground pin F-6; this makes the computer think that the cassette recorder is connected and the Play switch has been depressed.

Cassette-port I/O isn't the best way, but it sure is cheap. With just a minimal amount of experimentation, you can have your computer on the air and start exchanging programs!

ERROR-CORRECTING CODES

When transmitting data, it is useful to have some way of detecting errors and correcting them. There are many methods of accomplishing this. Let's begin with a discussion about parity.

When data are sent over a computer, they are usually encoded in any one of several standard computer "alphabets." The one used by most of the computer industry is called ASCII (pronounced askey). In the standard ASCII code (there are several variations of it), each character takes up seven elements called *bits*. When transmitted serially, the least-significant bit is transmitted first and the most-significant bit is transmitted last. In order to ensure that no bits were lost during transmission, a parity bit can be generated and sent as an eighth bit.

There are two types of parity: even and odd. In even parity, the parity bit is sent so as to make the *total* number of "1" or "ON" bits (including the parity bit) even. In odd parity, the total number of "1" bits is made odd. For example, if the ASCII code 1011001 was to be sent, the parity bit would be a zero if you were using even parity, and it would be a one if you were using odd. At the receiving end, if odd parity was being used, any byte with an even number of "1" bits indicates an error. For even parity, an odd number of "1" bits received means an error. There is no advantage to using even parity over odd parity; it would be nice if everyone used the same.

The software for generating or checking parity is very simple. They both involve the use of a logical exclusive OR (XOR). In case you are not familiar with the various logic functions, study the truth tables in Fig. 3. Note that the exclusive OR is similar to addition except that the carry bit is ignored. To generate the parity bit, perform the following algorithm:

1. Initialize a temporary data bit (0 for even parity, 1 for odd).
2. Take the first data bit and exclusive OR it with the temporary bit.
3. Repeat step 2 for the next six bits.
4. The temporary bit is now equal to the parity.

If you are receiving ASCII data, *compare* the generated bit with the received bit. If you are sending ASCII, *transmit* the parity bit as your eighth bit.

Now that you can detect errors, it would be nice if you can correct them as well. In order to do this, some redundancy must be introduced. The greater the redundancy, the more errors can be corrected, but efficiency will be sacrificed. The simplest method of error-correction is called the longitudinal-redundancy check (LRC). This is simply having a "vertical" parity across several bytes, in addition to the "horizontal" parity. For example, suppose the following bytes are to be transmitted (using odd parity):

00010000
10100001
00000001
11110001

The bit on the right is the parity bit. To use the LRC, a fifth byte is generated. (I simply chose to have the four-byte block; it can be any fixed length.) We'll use the odd system throughout. The sum of each column, except for the parity column, must be odd. That would make the LRC byte equal to:

10111110

The algorithm for generating the LRC is similar to generating parity:

1. Initialize a temporary byte (0 for odd, 1 for even).
2. Exclusive OR the first byte in the block with the temporary byte.
3. Repeat step 2 for the next three (or n-1) bytes in the block.
4. Generate a parity bit for the temporary byte, and put it in the MSB position.
5. The temporary byte now contains the proper LRC value.

Using the LRC to fix an error is simple. When data are being received, the computer is generating its own parity and LRC information. If what the computer generates doesn't match what was sent, an error has occurred. Suppose that the second byte in the example was received incorrectly as 10000001. The computer would know this was wrong because there is an even number of bits (2) and we are using odd parity. The LRC byte would also be wrong; 10011111 would be generated by the receiving computer while 10111110 would be transmitted to it. To correct the error:

1. Exclusive OR the generated LRC byte with the received LRC byte (ex. 10111110 XOR 10011111 gives 00100001).
2. AND the parity bit of this result with zero, thus setting it to zero.
3. Exclusive OR the resulting value with the byte that had the parity error.

That's all there is to it. The erroneous bit will be flipped back to the proper value!

The LRC certainly isn't the best method for error-correction, but it is the easiest to understand and implement. There are better methods, known as cyclic-redundancy checks (CRC), that can't be "fooled" as easily as the LRC. I will go into the CRC in a coming column.

Coming up also will be a detailed discussion of the various cassette-port standards and how to make them more reliable for over-the-air use. Also, we will be examining some inexpensive computerized methods of generating and decoding SSTV.

If you are doing anything with computers and ham radio, please drop me a line. I would also appreciate any comments regarding standards for computer-to-computer communication, expecially with regard to the encoding of computer graphics.

HAM HELP

I am looking for literature on Peltier electrodes. I am particularly interested in information on how to make them or use them to make a microsample osmometer.

Carlos P. da Costa MD, PhD
Rua dos Navegantes 541, Apt. 602
Boa Viagem, Recife
PE 50000 Brazil

I need a copy of the schematic and crystal information for an AN/PRT 4A transmitter.

Cletus G. Reinsel W3HWM
RD 1 Box 405A
Oil City PA 16301

I'm looking for schematics for the Wilson 1402-SM HT. I will pay for copying and mailing costs.

Robert Good KA0QBM
613 SE 89th St.
Berryton KS 66524

I would like to hear from anyone who has made receiver modifications to the Kenwood TS-700S or SP, and anyone who has constructed a 2-meter amplifier using the 4CX250 B-R or 8930.

Connie Mercer
HHB 32nd AADCOM
APO NY 09175

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
c/o 73
Peterborough NH 03458

In the last published installment of this column (July), I was leading up to a byte-by-byte look at how to implement a RTTY terminal program on several popular computers. A look was planned at several popular microprocessors in the 6800/6502 families, with the programs to be designed around these chips. Unfortunately, the powers that be, read editors, feel that such a topic is too esoteric for this column. So I shall continue to develop this program over the next few months on the side, and then try to make it available for those interested. Watch this column for an announcement. It will be a bit, though, because as observant readers may note from the top of this column, I am still moving and things get a bit tight now and then. But bear with me, OK?

Let's see what some of you are involved in these days. I am in receipt of a card from Dieter Kaerger, from West Germany, who is interested in various forms of encoded RTTY. Well, in the planning stage is an in-depth look at some of the schemes now in use, including but not limited to AMTOR. I would be interested to hear what the readership has to say on these exciting new techniques which allow almost error-free RTTY under less than optimal conditions. What equipment are you all using? What's good and what's a lemon? Let me know what you have found out and I will see if I can put all this combined knowledge into a useful form for all to benefit from.

This brings up the subject of manufactured equipment mentioned in this column. With few exceptions, I try only to write about equipment I have seen or a close friend has seen. I have tried to avoid rewriting press releases or ads—you can read those as well as I. Normally, the "New Product" blurbs you read in magazines are prepared from such manufacturer-supplied information and are likely to provide all the good points and none of the bad. I have now been burned a few times and will attempt to screen out the truth from the puffery.

Henry Townsend AF2U, up in Cape May NJ, drops me a line. No Cape May diamonds in the letter, though. I remember looking for those beauties on the beach years ago. Henry is looking for a circuit to display RTTY on a converted television set. We have dealt with this many times and my advice still stands. If you can convert the five-level RTTY to ASCII (and the multitude of articles to help you do that have been listed here many times), any of the available terminal boards will do just fine. Scan the ads; there are video display boards capable of building a stand-alone "dumb" terminal available for a reasonable price, and kits for less. I am sending Henry a list of articles published here in the past; those of you who are still confused about this topic should check through previous editions of this column.

Are you at all interested in a compilation of old columns? Drop the editors at *73* and Wayne Green Books a note and send me a copy, too. I would be happy to work up a compilation of the first five years or so of "RTTY Loop" (we are in our seventh *year now), but I need some feedback that* there is a desire to have the book published. This information is here and ready to be assembled, but the folks in Peterborough want to be sure there is a market before starting the project. Let us know.

Barry Travis N4FNZ, in Arlington VA, sends along a letter of distress. Barry has a monitoring oscilloscope, model OSA, using a 913 cathode-ray tube. He has been unable to find a source for this tube in the ads. Anyone out there in RTTYland able to help Barry should write him at 605 N. Irving Street, Arlington VA 22201. Good luck, Barry.

Another ham in need is Lynn Finch W2MSJ, from Port Crane NY. Lynn is using a Commodore 64 on RTTY and has a monitor which he would like to convert to use with the C-64. This was part of an ITT computer, is labeled STANSASB E25240 0000, and was apparently made in Sweden. Lynn is anxiously awaiting any information at Route 369, RD 2, Box 789, Port Crane NY 13833. Don't let him down!

People do help others. In June, I mentioned that Charles Hoppesch was looking for a RTTY program for the TRS-80 Model *III. I have a letter here from William* Buckingham, in Osceola PA, who advises of *The Disassembled Handbook for TRS-80*, a five-volume set from Richcraft Engineering which apparently contains a RTTY program for the TRS-80. I have not seen the book or program, but Bill indicates that it is quite a program and that he has it up on his computer. You might keep an eye out for this book in your local computer/ham shop. If I get more information on this one, I shall pass it along forthwith.

I would like to point out, by the way, to folks like Ernest Nyberg K4GYI, in Lake Worth FL, that this program is also adaptable to the old TRS-80 Model I. Now, this rig had its share of problems with TVI and RFI and the like. But it is a good machine underneath it all, and if you can lick the in*terference problem, this book may be* of some use to you as well. I would be interested to hear from you when you get the Model I on the air. That's not *if*, but *when!*

The VIC-20 has some new folks using it. One of them is SFC Lawrence (Skip) Barley, Jr., overseas with the US Army. Yes, Skip, you can use the VIC-20 on RTTY, but you will have to use a program designed for the VIC-20, as opposed to the TRS-80 program mentioned above or one for some other computer. We have touched on a few of these in the past and you mention in your letter that you will be looking at back editions of "RTTY Loop," so I hope you have seen some of the information we have printed. I have not had any feedback either way on the several hardware adapters on the market nor have I tried any of them. But watch this column for future information as it becomes available.

Regards to Dale Parfitt WA2YPY, a devoted 6800 user from West Palm Beach FL. Dale indicates that a score or more hams in his area are using 6800s and would like RTTY programming. Hang in there, folks, I hear you. I will have something for you in the not-too-distant future. And thanks for your support.

Hey, how many of you are using RTTY mailboxes of one sort of another? Why not drop me a short note, listing the boxes you are using, protocols, likes and dislikes, stuff like that. I will try to publish what I receive so that good ones get better and super ones rub off on the rest. Just drop a note to me in care of *73* for now, and be sure to enclose an SASE if you would like a personal reply. But be patient, OK?

AMTOR, remote mailboxes, ASCII—we have all come a long way from an old Model 15, haven't we? The range is huge, but every month I try to distill it down to potability here. Let's see what turns up next month in RTTY loop.

LETTERS

MAILBOX FULL

HELP! Because you were thoughtful enough to publish my letter (March) setting the record a little straighter about life and living in Latin America (particularly on the Emerald Coast of Colombia), I have been deluged with mail from your readers.

So, may I, through your "Letters" column, assure them I am most delighted with their responses and will eventually answer each and every letter? Muchas gracias!

Juanita Bird
Santa Marta, Colombia

DUSTY DESIRES

We would like to ask your assistance (and that of your readership) in a project that our museum is involved with. We have a need for our displays for World War Two US communications equipment. Specifically, we need both portable (manpack) and vehicular radio sets along with all related components including vehicle shock mounts. These will be incorporated into our displays to complete vehicles. Our needs do not include radios or components unique to fixed station, shelter-mounted, or aircraft application.

There can be no question that the quality and quantity of US communications equipment was a significant factor in the success met on the world's battlefields. We feel that it is very important that selected items of this material be preserved and displayed. We would very much like to hear from individuals who have such equipment, no matter how insignificant it may seem, and who would like to aid us in this project.

Terrill M. Aitken
Capt. SC ORARNG
Curator
Oregon National Guard
Military Museum and Resource Center
Camp Withycombe
Clackamas OR 97015

AMTOR WARNING

As you know, the latest form of RTTY communications to be of interest to hams is called AMTOR, which has been used by the maritime services. The AMTOR processor board converts the synchronous signals to standard Baudot 60- or 66-wpm signals for the terminal.

For a number of years there has been a video terminal advertised that has been quite popular in this area. It is a low-cost unit that operates in both the Baudot and ASCII modes at 45 to 300 baud. This is a high-quality unit that has been well worth the cost. I am referring to the Xitex SCT-100.

There are a few items in the SCT-100, however, that are problem areas. When the unit receives a quote character, it displays the numeral 5. When it receives an exclamation character, it displays a quote. Typing a quote character transmits an exclamation mark and, if you type an exclamation, nothing is transmitted.

The problem becomes major when using the SCT-100 with an AMTOR converter. The "over" signal used in TOR is quote/question mark. Since the SCT-100 will not transmit the quote, it cannot, therefore, be used with TOR. The "over" signal is not just an indicator for the other station to begin transmitting; it actually controls the TOR circuits and is necessary for mode A operation. I think that there are probably many SCT-100 users out there who will try to use their 100s and perhaps wonder why they will not function properly.

Bob Roehrig K9EUI
Batavia IL

Bob, stop griping about the problem and get me a modification of the SCT-100 so owners can cope with AMTOR—Wayne.

RYAN'S HOPE

Wayne, you're the "devil's advocate." I call you that because I'm sure that, had you chosen a career in the clergy of the Roman Catholic Church, you would have early on filled that post in Rome.

I feel that you are, *unfortunately*, at least fighting a losing battle in trying to reform the members of our mutual hobby with respect to their manners (I refer to the letter from Bill Skipper KØARG in the May '83 "Letters" column). It's impossible! You're attempting that which all the priests, rabbis, and other assorted clergymen over the past 10,000 years of human history have not been able to accomplish. After all, all hams (at least most of them, anyway), are members of the human race.

One need only listen in on 14.230 MHz sometime (that's where the SSTV folks hang out on 20 meters) for a while. Not only is there squabbling between those running SSTV and those who suddenly appear on frequency for other purposes (we won't even mention the habits of the DX and contest workers), but there's also even squabbling among the SSTVers themselves as to whether the frequency is for SSTV OSOs or SSTV "technical discussion" nets, etc. I've gone no further into this mode of our hobby than buying K6AEP's 7.4 SSTV program and probably won't, with all the squabbling. I can safely think of other modes to invest my dollars in (such as RTTY). No one can stop the squabbling—not even, should they try, the FCC. My, they even squabble over

which SSTV system is the best and knock, badly, what each doesn't have (or support). Now that's squabbling for you! In 29 years, in this hobby, I've never heard folks knocking other folks' equipment. It's an education in itself.

I can't agree with everything you apparently advocate, as I smoke cigars (no smoking) and am a retired police chief (some of your arguments against radar). However, I defend your right to speak out. Furthermore, I agree with your attempts to advance the hobby into the twentieth century (never mind the twenty-first) by pushing the various newer modes of transmission. Unfortunately, as John Edwards' "Fun!" column's annual poll results indicate, apparently the interest in any newer mode of operation (i.e., RTTY, SSTV, OSCAR, etc.) doesn't exceed 30%, and that only for the potential use of the OSCAR satellites. One gets the impression that, in reality, approximately 6-10% of hams are interested in advanced (post-1963) modes of operation. It's a pity, but considering the fact that it's a hobby and hobbies reflect the social habits of the predominant generation at the time, perhaps it's understandable. (I'm not knocking the younger generation, but simply making a statement of apparent fact. The next one, being brought up on home/school microcomputers, will be different.) (I wonder if all the CW enthusiasts have considered the fact that, as a mode, it's really digital!)

To reiterate, this is, after all, a hobby, and most hams drift in and out of activity, from mode (or interest) to mode throughout their hobby career, in varying cycles (almost like one's biorhythms). We are living in a world of increased specialization (look at the programming field, for example) and our hobby is becoming more varied daily. There will be more of this, as time goes on (your *73* for example, will probably become as specialized as *80 Micro* or *Hot Coco*). Don't fight it. Even *QST* and the league can't be all things to all people.

Enough of this. You and your publications serve a good purpose in the hobby, so whatever you do, don't get discouraged.

Joe Ryan WB5LLM
Florence MS

I dunno, Joe—once I saw everyone's slow-scan pictures I stopped tuning around 14,230, so I've missed the beefing. Me iscouraged? Ha!—Wayne.

MINI-DOOMSDAYS

I appreciate your many editorials attempting to increase the size of amateur radio. You have suggested more interest in the clubs on a local level, more reading of ham magazines, and more encouraging of computer hobbyists to join the ham fraternity. I have read every editorial in *73* for the last year and you have overlooked one very important recruitment tool: emergency communications.

You did mention ham involvement in doomsday communication in the event of a nuclear war, but I am referring to floods, tornados, hurricanes, etc. This is when the spotlight falls on radio amateurs and our ability to communicate during emergency conditions for the public welfare.

All amateurs should remember that assisting official agencies with emergency communications is part of our charter. As we begin to interface our computers with our rigs, let us not forget the valuable role this equipment potentially has in an emergency.

Wayne, I believe your editorials will show less frustration if you forget about the old cronies standing in the way of progress. I do not think it is wise to repeatedly exhort this older group to "get with it." My experience has shown me that it is fruitless to attempt to budge this segment of amateurs.

I think it is more critical to prevent enthusiastic new hams from becoming lackluster, disinterested, out-of-date amateurs. I have seen emergency communications provide that stimulus to many hams. Whether it is a training drill on a weekend or providing communications for a walk-a-thon or air show, these activities really encourage direct ham involvement in which the amateur can really see his or her contribution to the community. At the same time, the ham receives the thanks of local residents.

I trust I have not overlooked any of your efforts in this area, Wayne; if I have, please forgive my oversight. I thank you for publishing a great amateur magazine.

David Sweigert WB9VKO
Beeville TX

You're probably right about the old-timers. One of our advertisers called the other day to tell us that his ads in 73 out-pull those in QST by a wide margin because, as he put it, "too many copies of QST end up in convalescent homes." It is fun gearing up to handle emergencies and we should get what few youngsters we have involved with it. If we plan our emergency communications systems so that they will be able to work even after doomsday, then they'll be duck soup for ordinary disasters such as earthquakes and floods—Wayne.

MARS POTENTIAL

Your publisher has waxed eloquent on several occasions on what is wrong with ham radio and on what should be done to correct it. At times his zeal may have drawn him into simplistic or impractical solutions (e. g., I suspect that getting kids into high-school radio clubs is not the complete answer to the Japanese ascendancy in electronics and autos; there may be some managerial and political ramifications, too). But he touches on something for which there may be a solution in place and ready for development when he deplores the lack of an effective emergency amateur radio system. I refer to MARS.

Before throwing more brickbats at the Military Affiliate Radio System, consider what it is and what it might become. I have been a member of MARS for nearly 30 years and have served as State Director of two states, so I know the good and the bad of it pretty intimately. And I have developed some thoughts about what it needs.

What it does not need is further ignoring by the ARRL and other sources of support and publicity. MARS is "of, by, and for amateur radio operators" and deserves much more recognition than it gets.

If it were better, maybe it would get some of that recognition (and maybe it would represent more of a threat to the TCPN than it does). Its function of operating phone patches for overseas servicemen is well known and respected. But little else about MARS is heard. And, in truth, there is much about it that rates criticism.

Nevertheless, it is a network of dedicated amateurs, nation- and worldwide, with the equipment and training to operate in emergency conditions. More important, it has the *potential* to build on the framework of the system-in-being to make a formidable answer to the need for emergency communications.

What it needs is money and support. When I first joined, there were six regional directors of the system; now there are only three. Where each office used to have at least adequate personnel to handle the vast paperwork and hardware requirements, now the eastern third of the US is administered by one sole individual. This is a result of government cutbacks in funding and it is hurting the system. What is the source of funding? Congress, of course. Letters to your congressmen are needed.

One glaring fault in MARS seems like it would be easily correctable: the fact that there are three separate MARSes. They should be integrated. Each state has an Army, a Navy, and an Air Force MARS, and they can't talk to each other! But nobody in authority has been willing to take this one step that would improve MARS about 500% in traffic handling and bring an enlarged system into much more contact with technically-skilled operators. They're out there but, splintered as MARS is, there isn't too much incentive to get things going.

Even with all the shortcomings inherent in association with the government and the military, government *with support* can get things done. MARS membership is an aging population, but more support and a revitalized system would reflect itself in more aggressive recruiting. Young people are welcome in MARS but they aren't showing up. MARS languishes, badly in need of just a few sparks to set it off.

73 would do inestimable good if it threw its formidable clout behind MARS. MARS is perfect for some boat-rocking, which *73* seems to enjoy. You are not bogged down with old fogies that hate change. And you have influence. How about it: Give us some help? Twist some arms; boost us some; encourage hams to look into MARS; hell, even bad-mouth us if you want to. At least that's better than being ignored!

John A. MacGahan W2DJM
Haines Falls NY

MARS could get a new lease on life if some of the members would take the interest to write about it explaining what, if any, the benefits are from joining. And while I don't think I've anywhere suggested that getting kids interested in amateur radio is the entire solution to the Japanese problem, I'm not sure how MARS fits in as a solution either. If there are more benefits to joining MARS than costs, get the word out and you'll get members—Wayne.

BILAL

Some of my customers have found that it is very difficult to find me. They must be using old journals and are assuming that I am out of business. I'm not. My correct address and phone number are:

MEXICAN NET NEWS

During the past few years and presently, the North West Radio Amateur Club of Obregon, Sonora, has been operating the Mexican Emergency Net on 7.090 MHz, LSB, from 0300-0400Z (the time may change by an hour seasonally to seek optimum propagation for the coverage of the entire Mexican Republic.)

Its purpose is to handle emergency traffic, contact air, maritime, and land-mobile stations, and receive check-ins from amateurs throughout Mexico. We believe this net will be of value to the amateurs in bordering regions in the event of any joint emergency.

Christopher Petroff XE2BSG
Chihuahua, Mexico

Take your favorite H.T. out for a drive tonight.

VISA or MASTERCARD for same day shipment.

For $69.95 you get the most efficient, dependable, fully guaranteed 35W 2 meter amp kit for your handy talkie money can buy.

Now you can save your batteries by operating your H.T. on low power and still get out like a mobile rig. The model 335A produces 35 watts out with an input of 3 watts, and 15 watts out with only 1 watt in. Compatible with IC-2AT, TR-2400, Yaesu, Wilson & Tempo! Other 2 meter models are available with outputs of 25W and 75W, in addition to a 100W amplifier kit for 430MHZ. ✓382

BRITISH COMMONWEALTH AWARDS

Through the cooperation of the Radio Society of Great Britain, I was able to obtain complete details of this great organization's awards program.

The following rules and conditions apply to all HF certifications and awards issued by the RSGB and should be read in conjunction with those governing awards and certificates individually.

All members of the RSGB will be afforded awards at no charge. Others must enclose at least 6 IRCs for each award. Applicants within the United Kingdom must submit QSL cards directly to the RSGB to justify their claim. All others may use the general certification rule with an affiliated society of a national organization.

Endorsements will be given for all-phone, all-CW, and/or single-band accomplishments.

Commonwealth DX Certificate (CDXC)

This certificate may be claimed by any licensed amateur who can produce evidence of having made two-way communication with stations located in at least 50 call areas listed on the Commonwealth call area chart. All contacts have to be made on 14 MHz, and an additional 50 contacts must be made in Commonwealth call areas on other bands. In the case of "other" bands, a particular call area may be claimed only once, irrespective of the band on which the call area was worked. The other call areas do not have to be the same as those worked on 14 MHz.

British Commonwealth Radio Transmission Award (BCRTA)

This award may be claimed by any licensed radio amateur who can produce evidence of having effected two-way communication with stations located in at least 50 of the call areas on any band or combination of bands. A five-band endorsement is available for 50 call areas on 5 bands.

Worked British Commonwealth Certificate (WBC)

This certificate requires the applicant to work at least one British Commonwealth station located in at least five of the recognized continental areas as defined by the ITU and noted in the List of British Commonwealth Call Areas. For the purpose of this award, North and South America count as one continental area.

IARU Region 1 Award

This award may be claimed by any licensed amateur who can produce evidence of having worked stations located in IARU Region 1. There are three levels of operating achievements: Class 1 requires contact with all countries in IARU Region 1. Class 2 requires contact with 35 countries within IARU Region 1. Class 3 requires contact with 20 IARU Region 1 countries.

To be eligible, all contacts must be made after January 1, 1979. Special endorsements are given for single-band or -mode achievements.

Members of IARU Region 1 are: Algeria, Austria, Bahrain, Belgium, Botswana, Bulgaria, Cyprus, Czechoslovakia, Denmark, Federal Republic of Germany, German Democratic Republic, Faeroes, Finland, France, Ghana, Gibraltar, Greece, Hungary, Iceland, Ireland, Israel, Italy, Ivory Coast, Jordan, Kenya, Lebanon, Liberia, Luxembourg, Malta, Mauritius, Monaco, Netherlands, Nigeria, Norway, Oman, Poland, Portugal, Rhodesia, Romania, South Africa, Sierra Leone, Spain, Sweden, Switzerland, United Kingdom, USSR, Yugoslavia, and Zambia.

To apply for any of the awards sponsored by the Radio Society of Great Britain, forward your application along with the award fee of 6 IRCs to: C. R. Emary G5GH, Westbury End, Finmere, Buckingham Bucks, England.

Cheshire Award

This award is issued in three categories: Applicants receive a gold award for accumulating 50 points, a silver award for accumulating 30 points, and a bronze award for accumulating 15 points.

Contacts must be made with only radio amateurs in the Cheshire County of England and there are no band or mode restrictions nor any date limitations.

Points can be claimed for all valid QSOs according to the example in Fig. 1.

Should you contact an amateur who resides in the County Town of Cheshire in Cheshire County, you may claim double point value.

The fee for this award is US $3.00 or 10 IRCs. This includes postage of the award which is attractively printed on parchment with an embossed seal signifying the category.

GCR apply; however, the Award Manager reserves the right to request QSLs prior to issuance of the award.

Mode	UK Stations	European Stations	DX Stations
CW/SSB/AM	1	2	5
FM	1/2	5	10

AFRICAN AWARDS

F. van Greunen ZS1IT wrote on behalf of the South African Radio League (SARL) and provided details for their very popular African awards program. A detailed description follows.

All Africa Award (AAA)

This award, sponsored by SARL, is made available to DXers throughout the world. Below is a list of areas in Africa from which QSL cards will qualify to obtain this award.

Confirmation must be submitted for one contact from each of the six ZS call areas as well as one contact from Botswana (A2), Lesotho (7P8), and Swaziland (3D6), plus one contact from 25 different areas of the remaining groups of country prefixes shown below.

A list indicating callsigns, mode, date, and time must accompany QSL cards submitted. Applicants who belong to IARU-affiliated clubs or societies may have

their QSLs verified through their affiliated organization.

All stations contacted must be fixed land stations. Islands around Africa or its coast do not count for this award. All contacts must be made after November, 1945, with a minimum CW report of 338 or phone report of 33. This award is issued free to SARL members; it is $.50 US or 10 IRCs for nonmembers.

Countries List: Algeria, Angola, Sudan, Congo Kinshasa, Burundi, Rwanda, Somali Republic, Cameroons, Egypt, Eritrea, Central Africa Republic, Republic of Congo Brazzaville, Gabon, Chad, French Morocco, French Somaliland, Ivory Coast, Dahomey Republic, Volta Republic, Mauritania, Senegal, Niger Republic, Republic of Guinea, Gambia, Ghana, Kenya, Liberia, Libya, Mozambique, Nigeria, Zambia, Malawi, Portuguese Guinea, Sierra Leone, Rhodesia, Spanish Morocco, or Ifni or Rio de Oro or Spanish Guinea, Tangier, Tanzania, Tunisia, Togoland, Uganda, Botswana, Lesotho, Swaziland, Southwest Africa, Republic of South Africa (ZS1-ZS6), Transkei, Bophuthatswana.

Applications and the appropriate award fee should be addressed to the attention of: F. van Greunen ZS1IT, Awards Manager, South African Radio League, PO Box 3911, Cape Town 8000, South Africa.

AWARDS FROM CERTIFICATE WORLD

I was very pleased to receive a letter from a new subscriber and to learn of his new adventure of collecting various amateur operating awards. Meet Stu Herring WB5ULD from Fulton, Mississippi. Stu features some very attractive awards for the parchment pursuer.

Representing Certificate World, we find his awards are made available to all US and foreign amateurs for two-way communication in the separate award areas. All modes of communications are accepted with the exception of those contacts via repeater.

All awards have a fee of $1.00 each or 6 IRCs. GCR apply. Apply by sending your list of contacts to: Certificate World, Rt. 2, Box 72, Fulton, Mississippi 38843.

The Old South Award

This certificate depicts a scroll listing the ten states of the Old South. It is awarded for contacts from each of the states of Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Texas, and Virginia.

Old Man River Award

A certificate picturing the mighty Mississippi River and the ten states bordering the river can be yours for contacting the states of Arkansas, Illinois, Iowa, Kentucky, Louisiana, Minnesota, Mississippi, Missouri, Tennessee, and Wisconsin.

Mississippi State Award

If you thought your first Mississippi QSO was hard to get, try making a total of ten to earn this award. A state outline and statistics add up to an interesting award for your hard work.

Capitals of the United States

This one will not come easy. You must have two-way communication with all 50 US state capitals, plus Washington DC. Fifty-one QSOs will earn you an award listing some facts about the US Capital and proof of a lot of hard work and fun.

There's a good chance you may have already qualified for some of these awards. If not, good luck on earning them. Let Certificate World hear from you and be sure to tell our friend Stu WB5ULD that you read about it in *73's* Awards column.

SMIRK AWARDS

Ray Clark K5ZMS, representing the Six-Meter International Radio Klub (SMIRK), has forwarded some very impressive achievement awards for fellow six-meter enthusiasts to pursue.

To become a member of SMIRK, applicants must make 2-way contact by any normal emission with other members of SMIRK. US stations must log 6 contacts, while stations outside the US must log at least 3 member stations. All contacts must be made after October 14, 1973. Once this is accomplished, forward your claim along with $4.00 for a lifetime membership certificate.

Once a member, you then become eligible to apply for the other awards sponsored by this six-meter group. Separate awards are given for making contacts with 100, 250, 500, and 1000 SMIRK members, utilizing the same guidelines already mentioned. Cost is free to members of SMIRK.

And for those who want the ultimate challenge on 6 meters, SMIRK offers the DX Decade Award for having contacted ten DX countries on six meters. Endorsements are given for 15, 20, 25, etc., in increments of 5 DX country contacts.

To apply for the DX Decade Award, list all logbook information and enclose $3.00 for ten countries and $1.00 for each 5-country endorsement seal being applied for. For all correspondence with the SMIRK group, write: WA1KYH, SMIRK Award Manager, 18 Laurel Drive, Medfield MA 02052 USA.

ROCKWELL COLLINS

The amateurs at Rockwell-Collins will be manning ADØC within the Collins Telecommunications Products Division complex throughout the rest of the year (phone: 28600, 21300, 21355, 14280, 14210, 7275, 7190, 3950; CW: 30 kHz up). The station will commemorate the 50th anniversary since the incorporation of Collins Radio Company in 1933. A special QSL card will be available for amateurs contacting the station during 1983. QSL to Rockwell-Collins, Box 728, Cedar Rapids IA 52498.

CHELSEA FAIR CERTIFICATE

A special certificate will be presented to any ham radio operator making contact with the Chelsea Communications Club from August 30 through September 3. Contact can be made with WD8IEL on 40 and 80 meters from 2300Z to 0100Z. Send an SASE to 104 East Middle Street, Chelsea MI 48118.

OK CORRAL

On Labor Day weekend, September 3, 4, and 5, 1983, the famous OK Corral in Tombstone, Cochise County, Arizona, again will be the site of a special-event station. Operations will be carried on only a few feet from the actual site of the shoot-out between the Earp and Clanton factions. This station (KB7KZ) will operate in conjunction with the second annual Rendezvous of Gunfighters. Operations will begin at 1500 UTC, September 3, and continue through 2400 UTC, September 4, on CW and SSB. Frequencies as follows: SSB—28680, 21380, 14280, 7280; CW—21130, 7130. A certificate will be awarded to all who work us as well as SWLs. Please send a large 8½ × 11 SASE (40¢ postage) to KB7KZ, PO Box 36032, Tucson AZ 85740.

NORWALK OYSTER FESTIVAL

The Greater Norwalk ARC will operate a special-event station, WA1RXA, from the Norwalk, Connecticut, Oyster Festival on September 9, 10, and 11. Any ARS contacting WA1RXA will receive a special certifi-

cate upon sending an SASE to Joseph Beck, 26 Ambler Drive, Norwalk CT 06851.

Times: Sept. 9: 2200 to 0100 GMT, Sept. 10: 1500 to 0200 GMT, and Sept. 11: 1500 to 0000 GMT.

Frequencies: phone: 3890, 7240, 14305, 21385, 28600; CW: 3720, 7120, 14090, 21090, 28090.

BEAR BRYANT

The West Alabama Amateur Radio Society (WAARS) will operate a special-event station on Saturday, September 10, in commemoration of the birthdate of college football's winningest coach, Paul "Bear" Bryant.

WAARS will operate station W4WYP from 1300Z to 2400Z on that date. Frequencies will be the bottom 25 kHz on the General 40-15-meter phone band. The club will also work Novices on the bottom 25 kHz of the Novice band. The club will offer a handsome commemorative certificate of the event to any station worked by sending $1 and a large SASE to the West Alabama ARS, PO Box 1741, Tuscaloosa AL 35403.

STARVED ROCK RADIO CLUB

The Starved Rock Radio Club in Oglesby, La Salle County, Illinois, will operate their club station, W9MKS, on all amateur bands from their clubhouse on September 10 and 11. A suitable QSL is being designed for this period of operation, in celebration of 50 years of amateur radio in central Illinois.

JESSE JAMES DAYS

The St. Paul Radio Club (KØAGF) will operate a "railroad mobile" special-event station aboard a steam-powered train operating out of Northfield, Minnesota, during their Jesse James Days celebration. Operations will be from 1400 UTC until 2300 UTC each day, September 10 and 11. Frequencies: SSB—3.948, 7.267, 14.288, and 21.377. CW—3.552, 7.107, 14.057, and 21.057. A special certificate and QSL will be issued to those furnishing a 9 × 12 SASE (37¢ postage) and a QSL to those furnishing an SASE with 20¢ postage. QSL to St. Paul RC, PO Box 30313, St. Paul MN 55175-0313.

GEN. STERLING PRICE DAY

The Chariton Amateur Radio Society of Keytesville, Missouri, will operate KBØCC from 1400 to 2200 UTC on September 17, 1983, in celebration of the town's 150th anniversary and the annual General Sterling Price Day, honoring its favorite son of Civil War fame and governor of Missouri. Frequencies: phone—7.280 and 21.240.

LARGEST BLAST FURNACE

The Inland Steel Employees' Repeater Association is sponsoring special-event station KB9PQ, whose theme is "The Largest Blast Furnace in the Western Hemisphere, #7 At Inland Steel." The station will be set up in the Inland Steel parking lot and will be on the air from 1300Z Saturday, September 17, to 2400Z Sunday, September 18, operating all bands in the first 10–15 kHz of the General and the Novice portions of the band. The station will also be on 146.52/.52 FM. Certificates (a full-color picture of a blast furnace) will be available from ARS KB9PQ, 7605 Southeastern, Hammond IN 46324.

APPLE FESTIVAL

The Smithfield Apple Festival, held at Smithfield OH, is sponsoring a special-event station. Operation will be from 2300 UTC to 0400 UTC on September 23 and September 24, 1983. Operation frequencies will be: SSB—3.900 plus or minus 5 MHz; Novice—7.110 plus or minus 5 MHz. The station call will be N8CUX. Special certificates depicting the bed race will be sent to those who send a 4½" × 9½" SASE to Robert Carson N8CUX, 259 Hill St., Smithfield OH 43948.

NEW PRODUCTS

IC-751 HF TRANSCEIVER

Icom announces the IC-751 HF transceiver, featuring a new generation of technology and computer control. Icom's new CPU, with internal-battery memory backup, provides 32 memories with memory storage of mode and frequency, and the scanning capability to cover large segments of the spectrum very slowly, or to scan the memories by selected mode.

The IC-751 provides instantaneous band selection and has a 3-speed tuning system. Other features included are full break-in keying, passband tuning, notch filter, RIT and XIT with separate readout, FM built in as standard, a very steep-sided FL44 sideband filter, continuously adjustable noise-blanker levels, dual vfo operation, and all-mode squelch. A two-color fluorescent readout showing the frequency in white and the control functions in red, for visibility in all ambient light conditions, is standard. The IC-751 is equipped standard for operation from 12 volts dc, and there is an optional internal ac power supply.

For more information, contact *Icom America, Inc., 2112-116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

RTTY FOR THE VIC-20

Microfish Software Products has released two programs which use the Commodore VIC-20 as an inexpensive Baudot and ASCII RTTY terminal. These programs, RTTY3K and RTTY8K feature 60-, 66-, 75-, and 100-wpm Baudot, 110-, 300-, 600-, and 1200-baud ASCII, CW ID with the operator's callsign built-in, keyboard-operated transmit/receive control, and special-display-screen formatting for a more readable display.

These programs allow the VIC-20 to be connected to any terminal unit, commercial or home-brew, allowing flexibility in choice of RTTY equipment. Simple hookup instructions are given for connecting the VIC-20 to the TTL, RS-232, or current loop input/output of the selected terminal unit as well as the PTT connections to the transmitter or transceiver.

The RTTY8K version includes 10 large message buffers. These buffers are part of the program and do not have to be typed in or loaded from tape each time the RTTY program is loaded. All 10 buffers can be programmed and reprogrammed easily by following the instructions supplied. These buffers can also be changed easily while operating by using simple keyboard functions.

To eliminate repetitive typing, RTTY8K features three automatic messages. The automatic CQ message keys the transmitter, sends CQs followed by DE and the operator's callsign, sends the CW ID, and then unkeys the transmitter, all at the push of one key. Similarly, the automatic start-of-transmission message sends DE followed by the operator's callsign. The automatic end-of-transmission message sends the other station's callsign followed by DE and the operator's callsign, the CW ID, and then unkeys the transmitter.

On-screen status display is accomplished by an "intelligent cursor" that indicates whether Baudot or ASCII is in use, the speed, which message buffer is being sent, transmit or receive mode, and other special functions.

RTTY3K requires 3K of memory, while RTTY8K needs an 8K memory expansion. Both programs are available on cassette and include complete installation and operating instructions.

For more information, contact *Microfish Software Products, PO Box 920342, Norcross GA 30092.* Reader Service number 477.

THE TU-470 TERMINAL UNIT

The New Flesher Corp. TU-470 RTTY/CW terminal unit offers many standard high-performance features for your money. It receives up to 300 baud on all three shifts, provides TTL- and RS-232-compatible I/O including bipolar CW and PTT outputs for complete remote control and isolation of computer-level I/O keying.

Each TU-470 RTTY filter board is a high-sensitivity, high-Q, 3-stage, 6-pole active bandpass filter which provides excellent stability and sharpness. A signal-balance restorer circuit has been incorporated to allow reception of nonstandard RTTY shifts on mark only. The CW filter/demodulator has a 3-stage, 6-pole filter centered at 750 Hz for CW reception.

The TU-470 also provides crystal-controlled AFSK, FSK, a 170-Hz narrow preselector filter, built-in 20- or 60-mA loop supplies, autostart, threshold control, 5 LED indicators, bar-graph tuning, scope outputs, reverse receive, and reverse transmit.

For more information, contact *Flesher Corporation, PO Box 976, Topeka KS 66601; (800)-HAM-RTTY.* Reader Service number 479.

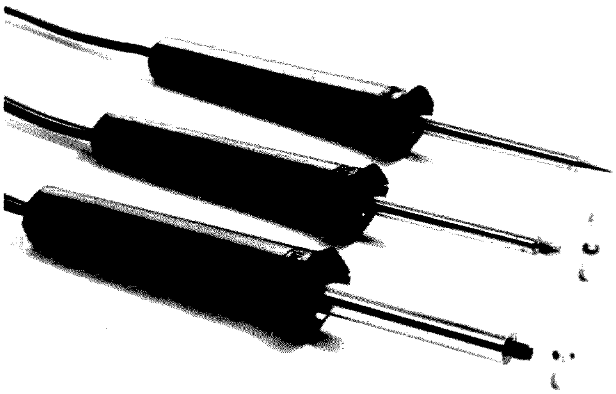
The MAXCOM high-speed antenna matcher.



New soldering irons from Ungar.

ANTENNA MATCHER

Magnum Distributing has introduced its MAXCOM automatic high-speed antenna matcher.

By using the latest in solid-state technology, MAXCOM will automatically tune one antenna from .3 MHz to 70 MHz with a vswr of less than 1.5, without external control leads, in either the dipole or long-wire configuration. MAXCOM matchers are available in three models covering 200, 1000, and 2000 Watts PEP. Their light weight and small physical size make them ideal for self-supporting dipole installations. (MAXCOM 200 and 1000: weight, 2 lbs.; size, 4.75" W, 3.75" H, 2.25" D. MAXCOM 2000: weight, 4 lbs.; size, 7.50" W, 4.75" H, 2.25" D.)

MAXCOM matchers are manufactured by Terramar Systems, Inc., of Fort Lauderdale FL and were initially developed for military and commercial applications that required extremely wide-spectrum, high-speed transmit and receive capabilities.

For more information, contact *Magnum Distributing, Inc., 1000 S. Dixie Hy. W #3, Pompano Beach FL 33060; (305)-785-2002.* Reader Service number 484.

FUNCTION BOARDS FOR S-100-BASED COMPUTERS

Industrial Computer Designs has announced four special function boards for S-100-based computers, together providing calendar, clock, alarm, timer, and 64-channel analog-digital-analog conversion capabilities.

The CCA-100 calendar/clock/alarm board can be used to display hours/minutes/seconds and day/month/year on a CRT, time events in second increments, and produce musical alarm tones over a four-octave range. Its brother CCT-100 calendar/clock/timer board can control events with 1/100th-second accuracy, keep track of computer time used, or calculate days elapsed between dates, all as hardware functions. Time/date information may be sent to a printer or stored as data, with all functions under software control. Both cards have long-term battery backup and utilize a minimal number of Z80/8080 ports for operation.

The D/A64-100 produces 64 analog outputs with 8-bit converter resolution, while the sister A/D64-100 board performs A/D conversion with similar accuracy. Voltages may be generated or read over a 0-to-5-V-dc range in 255 increments. The boards are port-selectable so that multiple cards may be used to create large systems as controllers for energy management, security, industrial control, or robotics.

ICD products are available through computer hardware distributors and dealers throughout the US and Canada, and will be supported by advertising in both trade and consumer publications. An owner's operation/service manual accompanies each card, which includes application and support software listings.

For more information, contact *Industrial Computer Designs, 31121 Via Colinas #1005, Westlake Village CA 91362; (213)-889-3179.* Reader Service number 482.

UNGAR INTRODUCES NEW SOLDERING IRONS

Three new low-priced "consumer" soldering irons with Thermo-Duric heaters have been introduced by the Ungar Division of Eldon Industries, Inc.

Thermo-Duric heating elements reach soldering temperature faster, use less energy, last longer, and take less space than earlier wire-wound heating elements. Since the heaters were developed for industrial soldering systems, the new "consumer" line has soldering qualities and dependability appropriate for electronics technicians and prices to attract hobbyists and do-it-yourselfers.

The CM-25 has an integral nickel-plated cone tip suitable for small and large connections. The 25-Watt iron heats to 750 degrees F. The 45-Watt CM-45 and 80-Watt CM-80 can use any of 11 standard Ungar screw-on tips, and have three-wire cords to prevent leakage current damage. The CM-45 comes with an iron-plated pencil-tip point. Operating temperature is 700 degrees F. The large-capacity CM-80 comes with an iron-plated chisel tip and operates at 800 degrees F.

Slimmer, cooler handles were made possible by the efficiency of the "Thermo-Duric" heaters.

Further information is available from *Ungar, 100 W. Manville St., Compton CA 90220; in Canada: Eldon Industries of Canada, Inc., 500 Esna Park Dr., Markham Ontario L3R 1H5; (416)-495-9407.* Reader Service number 481.

PERSONAL HAM-TAGS

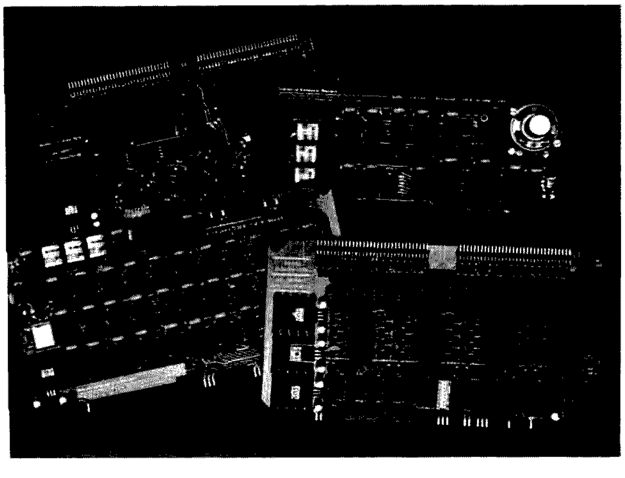
BHC, Inc., has announced its new "Ham-Tags." Ham-Tags are license plate frames personalized with ham radio callsigns. These frames are made from black molded ABS, the same material used for trim on most new cars.

A set of Ham-Tags consists of two black frames with white, permanent vinyl letters in the large imprint area. License plates differ from state to state, so you would have to check your plate to see if your call would go at the top or bottom of the frame. In states that have only one plate, BHC will furnish a frame for the rear and a plate for the front.

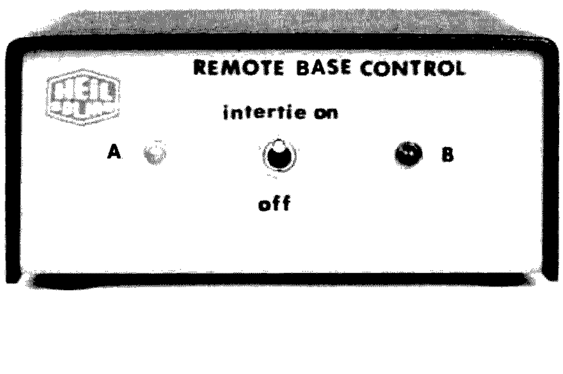
For more information, contact *BHC, Inc., 1716 Woodhead, Houston TX 77019; (713)-522-5755.* Reader Service number 483.

REMOTE-BASE CONTROL

A new intertie control has been introduced by Heil, Ltd., of Marissa IL. The RB-1 allows two-way control of two FM transceivers. A 2-meter transceiver can be connected to a UHF or 10-meter FM transceiver for remote-base operation. Sepa-

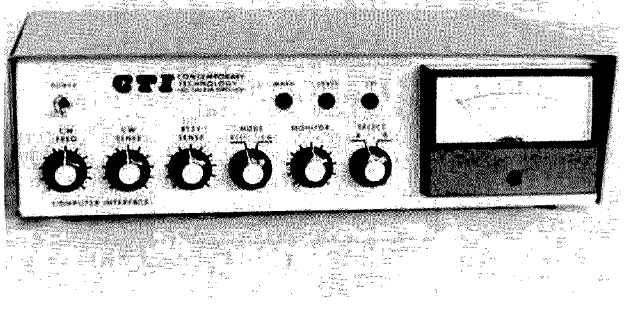


Function boards for S-100-based computers.



The Heil RB-1 remote intertie.

The Bird wattmeter field-strength plug-in element.



Contemporary Technology's TMC-1B computer interface.

rate squelch and audio lines are fed from each rig, as is the PTT control line.

As the squelch of one rig is activated, the RB-1 will turn the transmitter of the second transceiver on. The reverse of this also happens, allowing complete remote-base control between the two transceivers.

The RB-1 can also be used as a complete repeater control for simple repeater systems or emergency operation.

For more information, contact *Bob Heil, PO Box 68, Marissa IL 62257; (618)-295-3000.* Reader Service number 476.

PROKEY SOFTWARE FOR THE VIC-20

The Prokey (and Prokey Deluxe) Software turns your VIC-20 into a full-featured CW keyboard. Of the two programs, one is designed to run on an unexpanded VIC-20. This program will provide normal CW keyboard sending with a ten-character buffer and a visual indication when the buffer is starting to get full. It also provides the capability of storing three user-programmable messages which can be changed while the program is running. You can also display the stored messages in order to check them. An abbreviated version of the serialized-contest-number generator is included, and an electronic notepad will let you keep track of the station you are talking to.

The second program requires a total of 7K of user memory and therefore expanded memory for the VIC-20. This program includes all of the features for the basic program and some special additions. A built-in clock will send the time in Morse code with just a single keystroke; a real-time clock will display the time on the corner of the screen; the beacon mode will allow a beacon message to be sent at any interval up to 23 hours 59 minutes; the logging mode will display log information automatically when you send $\overline{\text{SK}}$; and a screen-sized buffer allows editing capabilities.

For more information, contact *Jim Grubbs K9EI, PO Box 3042, Springfield IL 62708.* Reader Service number 478.

WATTMETER FIELD-STRENGTH PLUG-IN ELEMENT

The latest addition to the line of plug-in elements used with Bird directional wattmeters is an extremely sensitive relative field-strength element. Model 4030 expands the usefulness of Thruline™ wattmeters in the field by helping to optimize the radiated signal of any transmitter from 2 to 1000 MHz.

It is easy to increase the reach of business or personal transceivers, to extend the range of HTs by tuning, adjusting, and positioning antennas for maximum meter indication on the host wattmeter.

Model 4030 employs modern broadband circuitry instead of the highly reactive resonant networks of most field-strength meters. The element consists of a flexible receiving antenna, a single high-pass network, and a variable gain rf amplifier/detector. A battery-saving feature turns everything off when the element is removed from the wattmeter.

Typically full-scale deflection is obtained from a one-Watt CW source at 150 MHz through a quarter-wave antenna 8 feet distant. Dynamic range is at least 30 dB, and battery life is 100 hours or more.

For more information, contact *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139.* Reader Service number 480.

MOBILE PRODUCTS FROM BEALE ELECTRONICS

Beale Electronics has announced several new products for the mobile operator.

The CH-20 mobile antenna, designed by W0CZR and modified by KD0U, is compatible with Hustler and Hy-Gain masts. The antenna consists of a resonator and whip which, when added to your mast, has an overall height of 10 feet. This antenna has a broad bandwidth and is designed to handle full legal power.

The DX-15 mobile antenna is also available. It is similar to the CH-20 antenna and also has an overall height of 10 feet.

A new mobile mast has also been introduced. It can be ordered in one 54-inch section, two 27-inch sections, or three 18-inch sections, or it can be custom cut.

The Power Cable Package includes all the connectors, wires, fuses, and plugs you need to connect a solid-state transceiver to your vehicle. The package also includes a cigarette-lighter plug for temporary installations.

Top it all off with the Beale magnetic mount. It has a 5-inch-diameter base and is compatible with standard HF mobile masts. The mount comes complete with coax, PL-259 connector, and cord for mast stabilization.

For more information, contact *Beale Electronics, PO Box 2641, Evergreen CO 80439.* Reader Service number 492.

TMC-1B COMPUTER INTERFACE

Contemporary Technology has announced the TMC-1B computer interface for RTTY/CW. The TMC-1B will work with most home computers, including Commodore VIC-20, Commodore 64, Apple, Atari, and more. Software for the VIC-20 is included at no extra charge.

Some of the features of the TMC-1B include auto-start circuit on RTTY with a variable control on the front panel—you can adjust it to print only when you are on a solid RTTY signal; LC-tuned-circuit filter with a Q of 300 which offers greater sensitivity to weaker RTTY signals and also is more selective with crowded band conditions; and CW sense and CW frequency controls which give a threshold setting to copy a CW signal. With the CW frequency-adjust control you are able to adjust your rig farther from noise; it also will allow you to use most CW audio filters.

CTI has a built-in monitor speaker to allow you to hear the signal as it is sent in CW and RTTY mode. Also, an external speaker can plug into the TMC-1B for a loop through from your rig (or rigs) to a speaker.

The TMC-1B interface uses a CW LED to tune in CW. Mark and space LEDs indicate that you are on the RTTY signal, allowing you to see mark and space on an incoming RTTY signal.

With CTI, there is a single switch between two rigs (HF and VHF)—no plugs and cables to move. And no need to worry about + or − keying since CTI uses reed relays on the output for compatibility. There is high front-end gain (90 dB) for a wide-range in volume adjustment.

Other features included in the TMC-1B are: an RS-232 interface, a built-in printer loop supply (just add an optional transformer and power relay for printer motor), and an amateur 170-Hz shift as well as a 425-Hz shift for monitoring commercial signals.

The CTI TMC-1B is solidly housed in an 11"W × 3½"H × 10"D metal case for rf shielding. Simple hookup used RCA jacks for hookup to transceiver. Just run a line to MIC, to PTT, to speaker, and to CW key. Only one cable to the computer. All plugs for the computer are supplied as standard. The TMC-1B will work up to 300 baud ASCII.

The TMC-1B is fully guaranteed for one full year on all parts and labor.

For more information, contact *Contemporary Technology, Inc., PO Box 1083, Salem OR 97308; (503)-399-1370.* Reader Service number 491.

HUSTLER ANNOUNCES FIXED-STATION ANTENNA

The all-new Hustler 220-MHz vertical fixed-station amateur antenna, designated the Model G7-220, was recently introduced by Hustler, Inc. The G7-220 marks Hustler's entry into the now popular 220-MHz band and complements their existing base and mobile amateur antenna line. The 7-dB gain of the antenna for both transmitting and receiving makes it the most powerful omnidirectional 1-1/4 meter antenna available. The all-new design keeps the signal radiation pattern at the lowest possible angle to the horizon for maximum efficiency and longest range.

The Model G7-220 has an swr of 1.5:1 across its entire 5-MHz bandwidth, with swr at resonance of 1.2:1 at the antenna. The radiating element is dc-grounded, and the antenna has a 50-Ohm base impedance.

This new Hustler 220 MHz vertical uses the best available corrosion-resistant materials for long life. Only Hustler uses all stainless steel hardware in amateur and professional products.

The 122" long vertical element and four 14-3/4" long radials of the G7-220 are made from high-strength, heat-treated aluminum. Each radial is 3/16" o.d. The N-type connector used on all new Hustler amateur verticals provides an all-weather seat and virtually perfect rf characteristics under all conditions.

The antenna weighs only 7 pounds and is easily mounted on any capable vertical support up to 1-3/4" o.d. Wind loading is only 26 pounds at 100-mph velocities.

For further information on this or other Hustler amateur products, write: *Sales Department, Hustler, Inc., 3275 North Avenue, Kissimmee FL 32741.*

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

group that puts out *Computerworld, Infoworld,* and so on...a company several times the size of my firm in sales. The date was significant to me because it was eight years to the day from when I called the editor of a small micro newsletter to come up and discuss starting a magazine—and we agreed to give it a try. Five weeks later, the first issue of *Byte* went to the printer. Those were five frantic weeks, I'll tell you.

Getting *Byte* started was exhausting work but fun. We'd just gotten it off to a good start when the editor and my office manager moved the magazine out in the middle of the night, a stunt which I still haven't gotten over.

The merger means that we'll be able to do more promotion of our current magazines. It means we'll be able to start more magazines—and I have a bunch of them all planned out. Each magazine is going to require a staff, so we'll be needing 200 or 300 people to help out—editors, writers, technicians, programmers, people for advertising sales, typesetting, graphic arts, circulation, data processing, and so on.

Then there are a number of special projects such as my planned technical/business college. We're going to need management teams to get these projects going and run them. Most of this is going to be done in New Hampshire, but eventually we'll be growing into other areas of the country.

If you are interested in getting involved with some exciting new ideas, you should get a letter off to me telling me what you think you might be able to do. I'm looking right now for nonsmokers with a history of enthusiasm and the ability to make things happen with a minimum of supervision.

There won't be any astronomical salaries when we are starting new projects, but we will plan to make it well worthwhile for those who are the most helpful in starting the new projects.

For instance, there are a number of products that I'd like to have made in Asia and imported for sale here. I've got the contacts in Asia to handle that end, but I need the people to handle the project from the New Hampshire end...setting up the advertising, importation, and distribution of the products. This should be able to grow into a substantial business by itself.

Why New Hampshire? Well, mostly because this is one of the best places in the country to live. The quality of life is wonderful and the cost of living is far less than New York or Silicon Valley. We still don't have any state sales or personal income taxes in New Hampshire. We're in a small town with all of the advantages of a small town. The people are friendly and the crime rate is so low that few people even bother to lock their homes.

If you are looking for the chance of a lifetime to get in on some new projects...and if you think you can hack it...let me know. You're going to have to prove you can get things done. We have no free rides here, just a bunch of enthusiastic people all having the time of their lives working hard and turning out first-rate products. We're working out of old houses, converted motels, barns, and so on. This is not IBM.

You can be old, young, black, white, red, brown, male, female, undecided, but if you smoke, please don't bother me, okay? The air up here is invisible and we want it to stay that way.

We need people who astound us by how much they get done, not people looking for a way to laze through life, producing more baloney than work. We've already tried a bunch of those people and sent them on to work for our competitors.

The merger means that we have a guarantee of the money we need to move ahead on as many projects as I can find teams to work on. And if we run out of projects to get started, I'll have more. I come up with an idea for a good solid project every few days.

When you think about it, by the time you put my six magazines together with those Pat is already publishing, we're a very strong combination. I think we'll be able to parlay this group into a pilot model of the college of the future or into perhaps an educational satellite television network.

Pat is much like me—full of ideas and enthusiasm. I think we're going to really make things hum in the communications field. Care to join us?

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

RADIOTELETYPE

Like most who became involved with radioteletype before the days of microcomputers, my entry into the world of the green keys was not an easy one. While I had no trouble conquering the technical side of the field, finding a functioning teleprinter at a reasonable cost was another story.

After several weeks of searching, it was best-friend Jonathan Bird WA2MJK (now KA0BYW) who located a Model 19 for me. The next Saturday, we headed over to the Garden State to pick up the unit.

I'll never forget the face of the fellow I bought the machine from as we told him we wanted to stuff the unit into my subcompact Mustang II. I'll also never forget almost losing Jonathan and my new machine halfway across the George Washington Bridge.

This month, FUN! looks at the world of RTTY. The column is dedicated to those who got their start in the days when you could tell a radioteletype operator by the musty, greasy smell of his shack.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) RTTY keyboard setting
5) Full or ______ duplex
8) Amplification factor
9) Adjustable aperture in SSTV camera
11) ______ QSL
12) Audio compression is said to add this
15) Terminal unit (abbr.)
16) Computer section (abbr.)
17) Computer memories
20) Partner to 17 across
21) Austria prefix
22) Slang for CPU: electronic ______
24) Transmitter-generated signal for operator
26) To empty buffer
28) CP/M, 3.3, UNIX, for instance (abbr.)
29) Trademark for teleprinter

Down

1) Local circuit
2) ______ pot
3) Interference type (abbr.)
4) Sweden prefix
6) Popular amplifier brand
7) 3.6125 MHz, 880 kHz, 1 GHz
10) Slang for unwanted output
13) Opposite to 1 across
14) No-keyboard TTY (abbr.)
18) ______ 32
19) Look
23) Discharge between electrodes
24) 170 Hz ______
25) To subject a component to an action
27) Slang for current unit or power booster
28) German prefix

ELEMENT 2—MULTIPLE CHOICE

1) Which of the following amateurs never wrote a RTTY series for CQ magazine?
 1) Wayne Green W2NSD/1
 2) Byron Kretzman W2JTP
 3) John Edwards KI2U
 4) Al Gorithm W2RY

2) At which of the following frequencies can you send data at 1200 baud?
 1) 17000 kHz
 2) 3.625 MHz
 3) 14.090 MHz
 4) 28.300 MHz

3) What does the FCC call Baudot?
 1) Murray
 2) International Telegraph Alphabet Number 2
 3) Morse
 4) The FCC never refers to Baudot

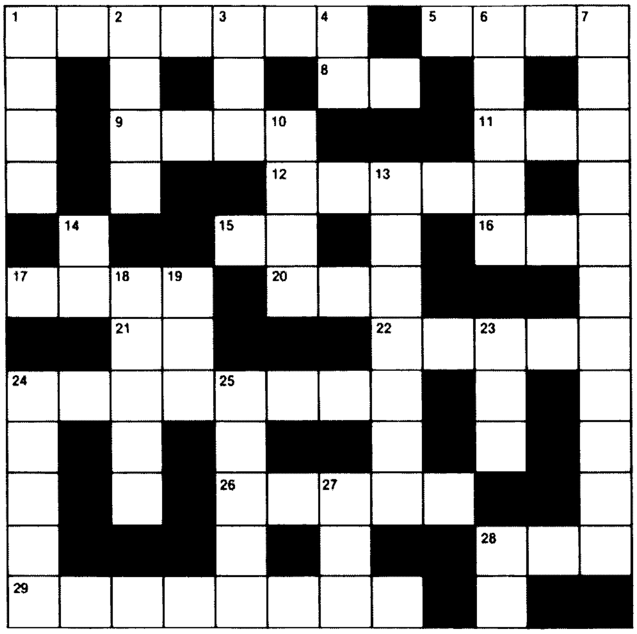


Illustration 1.

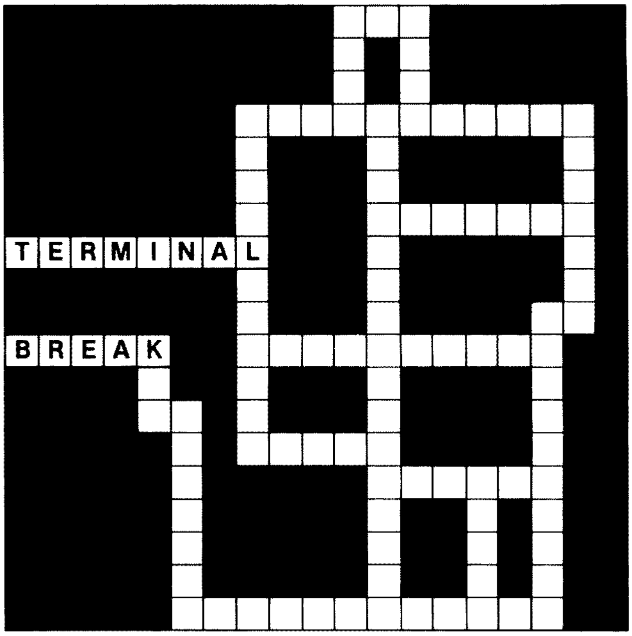

Illustration 2.

4) AMTOR is:
   1) A new, error-free digital transmission method forbidden on amateur frequencies.
   2) A new, error-free digital transmission method permitted on amateur frequencies.
   3) A type of nine-level code.
   4) A teleprinter brand.

5) Which of the following companies has never manufactured teleprinters?
   1) Olivetti
   2) Creed
   3) Seimans
   4) Remington

ELEMENT 3—TRUE-FALSE

	True	False
1) The two signals generated by RTTY are called "mark" and "trade."	______	______
2) The maximum RTTY signal shift permitted by the FCC is 850 Hz.	______	______
3) Baudot and Murray codes are one and the same.	______	______
4) ASCII is a seven-level code.	______	______
5) Baudot is a four-level code.	______	______
6) Novices can send RTTY within Novice bands.	______	______
7) General-, Advanced-, and Extra-class amateurs can send RTTY within Novice bands.	______	______
8) The Teletype® Company is owned by RCA.	______	______
9) Under traditional AFSK standards, the mark tone is the lower frequency signal.	______	______
10) One of the founders of the Teletype Company was Joy Morton, who also was founder of the Morton Salt Company.	______	______

ELEMENT 4—HAMAZE (Illustration 2)

Here's a new type of maze specifically geared to hams. The object is to start at "Terminal" and trace your way to "Break" by filling in the answers to the clues given below. To help you on the way, we've already given you the first and last clue answers. All words read either vertically downward or from left to right. Each new word is on a perpendicular angle to the previous word. Words join on a common letter. Good luck!

1) Computer operating console
2) RTTY power circuit
3) Energy
4) Tuning ______
5) Display unit
6) What this month's column is about
7) RTTY test letters
8) Printing fabric
9) Natural noise
10) What the brown fox is
11) Automatic reply system
12) Skyhook
13) German prefix
14) To joke with someone
15) Make and ______

SWR and POWER METER

DPM-1

MACAW's DPM-1 SWR/Power Meter has a frequency range of 1.8 to 150 MHz and a power range of 0-20, 200 and 1000W in three ranges. The DPM-1 is compact, lightweight and measures SWR and power simultaneously, only $49.95. Freight Prepaid Anywhere In U.S. Order by telephone or mail:

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—4 And the checks are still in the mail.
2—4 Below 10 meters you're stuck with 300 baud.
3—2 You expected something simple from our government?
4—2 So long, CW jammers.
5—4 And you thought the world began and ended with Teletype.

Element 3:
1—False Mark and space. Trade and Mark are the Smith Brothers.
2—False Nine hundred is the magic number.
3—False A rose is a rose is a . . .
4—False Nope. Eight-level.
5—False Nope. Five-level.
6—False Not yet, anyway.
7—True Let's all confuse the Novices.
8—False AT&T.
9—True Mark: 2125 Hz, Space: 2975 Hz.
10—True Could I make something like that up?

Element 4:
See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or one-half point for each question correctly answered.
Element 2:
Five points for each correct answer.
Element 3:
Four points for each correct answer.
Element 4:
Twenty-five points for the completed puzzle, or one point for each word solved.

Are you a friend of the green keys?
1-20 points—You run a CW net on 14.090 MHz.
21-40 points—Know a friend who used to own a Model 12.
41-60 points—Casual operator.
61-80 points—You keep an oil can on your night-table.
81-100+ points—You copy RTTY by ear.

HAM HELP

I am looking for a manual and schematics for an SG12 1800-4400-MHz signal generator. It was manufactured by Empire Devices, Inc.

Bill Stevenson WB3FZV
PO Box 518
Ridge MD 20680

Wanted: schematic for the KLM model 10-160BL 2-meter amplifier and schematics, cables, connectors, and control head for the Motorola U43GCT-1010B transmitter, type CC3006. I also need the solid-state power modules, both low and high voltage, for the T-195B transmitter. And I would like to hear from anyone who has converted the R-392 receiver to solid state.

Tommy Norris KA4RKT
Rt. #1, Box 412
Auburn KY 42206

I need the first part of the assembly manual for the Heath GR-269 color TV. I bought this kit in Mexico, but all of the PC boards and their parts are missing. I have all of the other manuals except the one describing the PC boards. I also need information on the Venus SS-2 TV camera.

from page 78

procedure, and a 9-month freeze on issuing new licenses.

There is an increasing interest in VHF, especially 2 meters. Being in Region 1, we are allowed only 144-146 MHz. 146-147 MHz is a popular commercial band since relatively inexpensive amateur rigs can be used on these frequencies. The first attempt at using a 2-meter repeater was in 1978 when a makeshift repeater was set up in Monrovia. It was not very satisfactory, with limited coverage and frequent breakdowns, but it was a beginning. Then the Bong Mine ARC installed a repeater in 1979 at their commercial site on the top of Bong Mountain at 900 feet altitude. It operates on 145.1 in and 145.7 out on a 7.5-dB gain vertical at 20 Watts output. It has five-county coverage (half of the counties) if proper power and antennas are used.

My path to Zorzor (pronounced zaw-zaw) is the longest path of anyone working the repeater. It is 90 miles over hilly/mountainous terrain. I definitely have the most exotic 2-meter antenna in Liberia. With the help of EL2FE, EL2CA, and the *ARRL VHF Manual* and *ARRL Antenna Handbook*, I constructed a vertically polarized rhombic, 58 feet on a side. It is fed with 300-Ohm ladder line and then matched with a universal stub into a 4:1 coaxial balun and a short run of RG-8/U into the shack. The rhombic is unterminated and bidirectional. It is easier to construct that way, and there is a rather unlikely chance that I will ever be bothered by QRM from 3X only 3 miles behind me. This type of antenna might be very useful for an American ham in a rural area with poor repeater coverage trying to get into a distant repeater.

Getting 2-meter equipment in Liberia is a real problem, especially for Liberians. If there are any repeater clubs or VHF enthusiasts that would like to help promote 2-meter activity in a developing country by sending old but serviceable crystal-controlled rigs that are lying around, please contact me.

Tom Viseh EL2AV has done the first OSCAR work from Liberia. On July 12, 1979, he made the first Liberia-US contact using OSCAR 7, which is about the maximum distance possible. Tom lost interest after his initial success since most of the time "there was no one to hear but myself," and since Tom left, there has been no one to fill the vacuum. I have some interest in OSCAR, but time and equipment are the limiting factors.

For many years, the West African Net has met on 7.060 at 0700Z on weekdays and 0800 on Sundays. This net is quite active and is mostly EL with some regular 9L and TU and occasional XT, 5U, TY, 9G, 6W, 3X, and maritime mobiles.

Liberia has been independent for 135 years and Liberians were probably the first black Africans to be licensed as amateurs. Historically, the first Liberian amateur was John Lewis Cooper who worked for P&T and was licensed about 1938. It seems that some expatriates may have preceded him by a few years but the history is not clear as to who was actually the first ham in Liberia.

The next group of Liberian amateurs was licensed in the 40s and included Henry Grimes EL2M, Robert Taylor EL2H, and Samuel Butler EL2L. These people are presently alive but inactive. In the 50s came Sewell Brewer EL2S, who presently works for the ITU in Geneva. The longest-licensed, presently active amateur in Liberia is Sam Watkins EL2P, who was first lincensed in 1956. Sam has been a key figure in the success of amateur radio in Liberia as the Assistant Minister for Telecommunications.

Walcott "Ben" Benjamin, Sr. EL2BA is the individual I consider Mr. Ham Radio in Liberia. He has been a powerful force behind amateur radio, acting as president of the LRAA and looking after our interests on the domestic and international scenes. Although a busy businessman, he always has time for amateur radio. He is a member of the IARU Region 1 division executive committee. He was an observer with the Liberian delegation to the WARC in Geneva and was a strong force behind the scenes which made the conference a success. He is constantly driving around the country helping to administer tests, and generously loans his personal equipment to those in need. He often buys equipment from departing hams because he doesn't want to see a good rig leave the country and somebody may need it in the future. He runs the QSL bureau and goes personally to LTC to assist others in getting their first licenses or even to renew their licenses. His list of contributions is unending. He has been licensed since 1968.

Other prominent Liberians are Jacob "Jake" Cisco EL2C, first licensed as EL4E in 1970. Jake is Chief Pharmacist for the Ministry of Health and is the man who helps get drugs for our hospital and many others. Ashley Rennie EL2AR was licensed in 1970 as EL4NA and is Communications Manager for the Firestone rubber plantation in Harbel. Henry Hali EL7E is a chemistry teacher at Cuttington University College in Suakoko. Henry was first licensed as EL5NA in 1971 and is very active on 20 meters.

A promising new addition to the Liberian ham community is Kokulo Waiwaiku, a young doctor from Zorzor who worked with me for a year after graduating from medical school. He was my personal recruit into ham radio. First licensed as EL5NB in 1981 and now EL2CQ, Kokulo is presently specializing in pediatrics in Monrovia.

Steve Mmari EL2EM is a Tanzanian who recently finished his studies in physics at the University of Liberia and is quite active. Steve is one of the few Tanzanians—if not the only one—to have a ham license.

Expatriates like myself have a fairly high turnover and usually stay for only 2-4 years. Americans make up the largest number of expatriates. They most likely would be missionaries like myself or sponsored by the US government, such as Voice of America staff, embassy personnel, and development people. Gale "Lee" Ruff EL2FE is one of the most prominent expatriates and is known as "EL2 Fix Everything." Lee has been in Liberia over 10 years and is the top engineering man at the Firestone rubber plantation in Harbel about 50 miles down the coast from Monrovia.

Operating from Liberia is enjoyable. The country isn't on the 10-most-wanted list, but we are constantly informed that we are the first EL contact, and prefix hunters go crazy with EL5 since there are only three of us. Pileups can be generated quickly when there are strong signals during popular operating times, especially with Europe and Japan. The best operators in a pileup are the Japanese, North Americans, and northern Europeans, in that order. The worst are the southern Europeans, eastern Europeans, and South Americans, in that order; operating under heavy pileup conditions with southern and eastern Europeans is impossible without operating split, and often I just shut down. However, unbelievable pileups can be handled without a problem on simplex with Japanese stations.

When signals aren't strong and during off operating hours, often you can call CQ without an answer, or generate a short string of QSOs which trail out and stop (are you listening QRPers?). Fortunately, we aren't so rare that you can't make a QSO with your buddies without being interrupted. We are, however, often asked for signal reports during short breaks, which is not too bothersome.

Stateside propagation is most reliable on 20 meters between 2100 and 0800. I usually keep a sked with my QSL manager, K3RB, at 2200 with universally good results. 15 meters can often be good during those times but drags out a little later in the morning, and quite reliable skeds can be kept at 1100 on this band. The problem with 15 and 20 meters is that they get good when a working family man should be in bed. That's why you hear Africans protesting all the time that they want to go to bed. When 10 meters is open it is usually between 1100 and 1900. On 40, 80, and 160 meters, nighttime is, of course, the best chance for DX, and to the US it is usually early morning before sunrise (0300-0600). Heavy QRN in the tropics quickly dulls your enthusiasm for the low bands.

There can be some nice long-path openings on 20 meters, usually into the West Coast, between 1300 and 1800. I ran a beautiful patch on 1400 MHz by this route recently to my brother-in-law in California. The band is more consistently open into the Pacific, and I once ran a patch into Guam at about this same time.

Other interesting openings include the very consistent 20-meter path to the Pacific and long-path VK at 0700-0900.

Walcott "Ben" Benjamin EL2BA, Kokulo Waiwaiku EL2CQ, and Steve Mmari EL2EM during an antenna-raising party for Kokulo (who erected a home-brew quad on a home-brew guyed tower).

Larry Johnson EL5F is seen here operating Yaesu equipment in his bedroom. Larry is translating the Bible into Kisi, which is the same ethnic group that Henry EL7E comes from. These two guys are certainly the only hams to ever carry out a QSO in Kisi.

Oscar Ocampo EL9A is a Filipino who keeps a regular sked with his DU buddies on this long-path opening. Sometimes there is an unbelievable pipeline long-path into JA at this same time on 15 meters. 15 is good to Africa and Asia in the afternoons between 1600 and 2000. People don't realize how close Liberia is to Brazil, and there can be some tremendous signals from PY on any band at almost any time. EA8 puts in crushing signals. The bands seem to be open almost always to Europe, which is a piece of cake. ZL is over the South Pole and for some reason is difficult to work.

We have ten call numbers. Each of the nine counties is designated a number 1 through 9. (Keep in mind that Liberia is a small country about the size of Indiana and has only 2 million people.) Most hams are in Montserrado County, which is EL2 and includes the capital, Monrovia. My county, Lofa, is EL5. It is the largest in the country and is nearly the size of Massachusetts. The LRAA offers a Worked All Liberia Award (WAEL) if you can confirm all 9 counties with contacts on at least 3 bands. It is not that easy, as all the counties are not presently active.

ELØ is maritime mobile since Liberia has a very large merchant marine. There are only a handful of ELØs and the suffixes all begin with A. Most ELØs are bootleggers; and they usually pick a callsign which *doesn't* begin with A, so they are easy to spot.

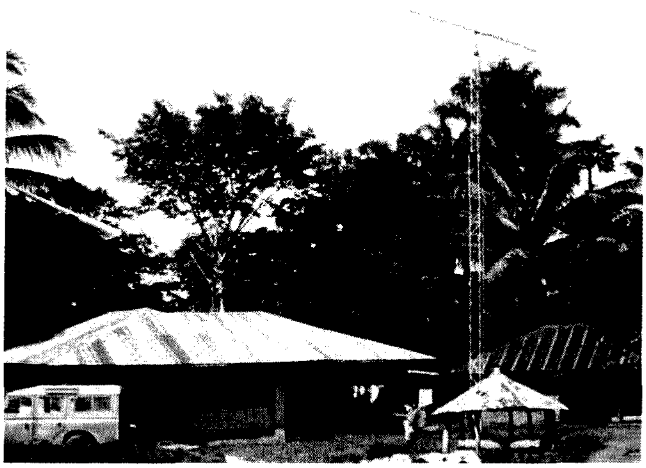
My position as Chief Medical Officer at Curran Lutheran Hospital in Zorzor is very challenging. Our hospital was started in 1924 and has 120 beds. It is hard to imagine, but there wasn't even a road to Zorzor until 1958.

My training is as a specialist in internal medicine, but my job includes everything that walks in the door including surgery, pediatrics, obstetrics, public health, and even chemotherapy. Other things, not usually included in a doctor's job description, include creating a homemade solar water heater, maintaining 15 old Heathkit/HF mission radios, repairing electrocardiographs and spectrophotometers, designing and supervising construction of buildings, and almost anything else.

Amateur radio is a great hobby and has proven to be invaluable for the hospital as well. We have had emergency situations caused by breakdown of critical equipment such as an autoclave for sterilizing surgical instruments. The generous phone-patch assistance of US hams has gotten replacement parts to us in as little as seven days rather than the 2-3 months that conventional methods would take. Another occasion where ham radio saved the day involved a severe eye injury to a blacksmith caused by a splinter of iron (wear your safety goggles). A phone patch to an opthalmologist in Pennsylvania allowed my colleague and I to perform eye surgery which saved the man's eyesight.

Our hospital has a long tradition of ham radio over the years. The maintenance chief in 1972, Dave Urfer EL5B, ran emergency communications with the Centers for Disease Control (CDC) in Atlanta during that year's Lassa fever epidemic which killed 4 people and left 2 completely deaf. This won him a medal from the Liberian government and a page in *73* magazine. Four other doctors who have worked at the hospital are hams.

Hamming is a relaxing hobby for me, and I enjoy construction projects, low-key DXing, and rag-chewing. It is also amazing what help a guy can get if he only asks another ham. If I have a technical problem, I can usually find the answer, anything from aircraft antennas to castrating pigs for a local agricultural project.

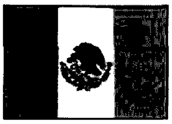


QTH of Larry Johnson EL5F, which is located in Boya less than half a mile from the Sierra Leone border. Boya is about a 5-hour drive from Zorzor when the roads are passable.

My HF rig is an Icom 720A which I recently acquired from a departing ham. I have found it to be as nice as it looks. It doubles as a general-coverage receiver and allows me to pick up football games and my favorite radio program, "All Things Considered," via the Armed Forces Radio and Television Service (AFRTS). It also serves as a frequency standard for my workbench. I have a Clipperton L amplifier which really helps, but it just blew a transformer and I'm waiting for the $145 replacement. I brought a Heights 64-foot, aluminum, foldover tower with me and use a Mosley CL33 tribander at the top of the tower. There is an 8-element quagi on a 4-foot mast above the tribander. I use a half sloper on 80 with a trap for 40 meters. I made a half sloper for 30 meters but was unable to get the swr down satisfactorily, so I am working on a rotatable shortened dipole. My vertically-polarized 2-meter rhombic for repeater work is 109 feet front to back and stands off the side of the tower.

The hospital has two 75-KVA Caterpillar diesel generators which supply electricity to the hospital compound. Diesel fuel is $3.00 a gallon, and spare parts are expensive and difficult to get. We presently have fairly reliable power for 21 hours a day, but I run my complete station except for the HF linear amplifier from a 120-Amp-hour battery with a 10-Amp battery charger. This gives me uninterrupted hamming enjoyment.

I hope you have enjoyed this ham-radio tour of Liberia! On behalf of the vigorous amateur community in Liberia, I invite you to work us on the bands and learn something more about our country.



MEXICO

According to Aztec mythology, Teotihuacan is where the gods came together to create the sun and the moon. A giant pyre was made and the poor but brave god, Nanauatzin, threw himself fearlessly into the sacrificial fire, thus becoming the sun. The richly-dressed Tecciztecatl, who had boasted of his bravery, hesitated before casting himself into the flames and thus became the pale moon. His light was now only a reflection of the sun's rays. From this legend came the names of the two largest pyramids of Teotihuacan, also known as "The City of the Gods."

DXpeditioners (left to right) Jesus, Leobardo, Daniel, Freddy, Gabriel (photographer), Mark XE1MKT, Ruth XE1MKT, Elvia, Lizzy, Wendy, Joe, Renee, and Chris.

Teotihuacan is the most widely known of Mexico's major archeological zones. Located about 42 miles northeast of Mexico City, the area covers 91 square kilometers. There you will find majestic pyramids of all sorts, temples, and courtyards. Some archeologists estimate that Teotihuacan had some 125,000 people living there, making it one of the largest cities in the world of its time—in the third century BC.

It was more than 2,300 years later that my XYL (Ruth XE1RBT) and I obtained special permission from the National Institute of Anthropology and History in Mexico City to occupy the top of the Pyramid of the Sun (65 meters high) for a 24-hour QSO. We asked for the date of February 12, 1983—our sixth wedding anniversary!

What a way for a married couple of hams to spend their wedding anniversary! Within all those QSO pileups there would certainly be someone who would ask why—and we would be able to answer (and delightedly remind ourselves) that it was just for the fun of it!

The first obstacle that we had had to overcome was getting permission to undertake this expedition to the archeological zone. There is nothing like doing things properly right from the very beginning, so a detailed written petition was presented to Lic. Pablo Elhore Garcia, Director of Legal Matters for the National Institute of Anthropology and History in Mexico City, and Emigdio Arroyo Garcia, Administrator of the Teotihuacan Archeological Zone. The matter was considered and, fortunately for us, approved! Then the real fun began!

February 12 was a Saturday, so we decided the 24-hour QSO would begin that day at 8:00 am and end on Sunday, February 13, 1983, at the same hour. Picture rights were obtained by the Institute, camping equipment was purchased at once, and Gabriel Stadtler (a good close friend of ours) got his camera equipment together and started making a study so as to capture our DXpedition on film, step by step, for *73* magazine (and for our family album, filed under "wedding anniversaries," with the theme: "Just For The Fun Of It"). I made out my list of the radio equipment and antennas that I would be using.

It just so happened that around preparation time I got together a parasitic beam that Ralph Bilal WDØEJA made especially for me in order to work the 15-meter band. I had never before owned a parasitic beam or any other antenna that works by inductance. Results: excellent! I was completely satisfied with its performance, especially because I could cover the entire band and stay within a 1.5:1 swr. This three-element, 15-meter parasitic beam has a coil on each end of the elements. Each is a 15-meter antenna in itself. There is the driven element that is excited directly through the transmission line (50-Ohm coax). The other two elements, each with its antennas, are parasitic and work by inductance from the driven element. The array is a combination of six 15-meter antennas, two on each element. Each antenna is tuned separately by moving the stub on the end of the coil until the lowest swr is reached on a designated frequency. The other five antennas have to be disconnected in order to tune up each one separately.

When all six are tuned up, they are connected up again and you have six 15-meter antennas working on just one beam! The boom is 8'2", excellent for Field Day use without getting into the "big array," and is made out of 7/8" aluminum tubing. The

Thawing out early Sunday morning on top of the Pyramid of the Sun, with sunrise in background.

Returning to ground level.

elements are around 12" long, with the radiating capacitor at the end.

Ralph manufactures three standard Isotron antennas and makes antennas for other spectrums of the 20-meter band for individuals who request them.

Thinking of the cold weather and possible battery-power loss during our 24-hour QSO, I worked on getting together a battery charger, using a small gasoline engine, voltage regulator, and alternator. However, time was pressing and I couldn't locate the gasoline-powered engine, so, knowing of the high winds on top of the pyramid that we would later climb, I mounted fan blades to a wooden structure along with the alternator and voltage regulator. However, our two 12-volt car batteries were enough, and I did not suffer battery loss. We did not have to use the charger system although we could have: When we first reached the peak of the Pyramid of the Sun, winds were high and so were the revolutions of the make-shift contraption that I called an emergency charger.

The day finally arrived for our expedition and we set off to Teotihuacan. With the help of local officials of the archeological zone there, our initial campsite was sought out, ending up right at the rear base of the Pyramid of the Sun. The pyramid stands 65 meters high, although originally, with a temple located up on top, it was said to be 10 meters higher. It has a volume of one million cubic meters, and each of its sides is 225 meters long at the base. Its main facade is situated 15°30' east of the astronomic north.

There we set up our tent and the boys and I got to work on our antenna setup. Ralph's parasitic beam was immediately put together, mounted, and tuned up. I used a two-piece, 9-foot television antenna mast. On its point we mounted a Ringo Ranger two-meter vertical antenna (made in Mexico). Well, there we had it for 15 and 2 meters, so up with the half-wave dipoles, using Hy-Gain's 1:1 baluns, for 40, 20, and 10 meters. We used a few local tall trees to hang them between.

Our permit was for us to transmit from 8:00 am until 9:00 pm within the archeological zone. I was told that over 30,000 tourists visit the area in just one day! So I discreetly began my 24-hour QSO at the back side of the Pyramid of the Sun until visiting hours were over. Then at 7:00 pm there was the first of two beautiful sound and light spectacles that take place twice nightly (except Mondays and mid-October to mid-May). We had to wait until 9:00 pm, therefore, to make our climb to the top and set up camp there, leaving part of our expedition group at our base station with two-meter equipment (Kenwood's TR-7850 and two handie-talkies, one Kenwood TR-2500 and an Icom IC-2AT) for our own intercommunication.

Running in front of the Pyramid of the Sun and leading right to the Pyramid of the Moon is the Old Road, or Highway of the Dead; it was named as such because many human skeletons have been discovered along it. That was our entrance way to the stairs of the Pyramid of the Sun at 9:00 pm, sharp. High winds and cold air greeted us as the six of us slowly made our climb to the peak, loaded with camping gear, radio gear, antennas, transmission lines (feedlines), 12-volt batteries, my "emergency wind-powered charger" contraption, food, serapes, and heavy clothing. A local official from the archeological zone was assigned to stay with us all night long. Another was kind enough to illuminate the entire 65-meter-high stairway with an airplane headlight that he had mounted to his pickup. Good old "Jose Luis" was there when we needed him the most! The Teotihuacan tribe had built these pyramids with some dangerously-steep stairs. Our aim was not to look back until we had made it to the top!

After a few rest stops we made it to the peak, quickly got organized, and began setting up the tent and the antenna system. Have you ever tried erecting a tent and a 9-foot mast with antennas up on top of a 65-meter-high pyramid with high winds in freezing weather? Tent rope was stretched out to different angles and wrapped carefully around protruding blocks of the pyramid (you just don't start pounding tent stakes into a 2,000-year-old archeological monument). We had to be extremely careful not to deface the site in *any* way.

That was just half the fun. Once the tent was set up, we took turns holding up the 9-foot mast as two others tied down the ends of the dipoles, using them as guying wires as well. The others thawed out some within the tent until it was their turn! Oh, what fun! (We saved ourselves plenty of work by using the dipoles on the mast as guying wires. We used the U-clamp provided by Hy-Gain with the 1:1 balun, fastening the balun to the mast one way and the other balun crossing over for a four-point counterbalance when all was tied down.)

"OK, *everybody* inside now!" was shouted. There was a quick scramble for a good spot in the tent as I announced over 2 meters to the group below and other local hams that the continuation of the 24-hour QSO would begin.

After wrestling for so long with those high winds and cold weather, to our surprise everything calmed down suddenly and we had a quite unusual silence until early morning, with the exception of those wonderful sounds carried over to us through radio wave activity!

It was one pileup after another! Real fine propagation! I had some nice conversations on 20 meters with stations such as VK3AQN (Fred in Melbourne, Australia), ZL2AJR (Gordon in Waikanae, New Zealand), and TI2MAO (Miguel in San Jose, Costa Rica), and on 10 meters, with KP4AAN (Pedro in San Juan, Puerto Rico), HK1ESZ (Edward in Cartagena, Colombia), WA4JUP (John on Merrit Island, Florida), and VE3IPP (Bob in Toronto, Canada). We QSOed with dozens of states in the US on 40, 20, 15, and 10 meters and had pileups from islands near Japan and off South America.

Upon scanning the bands, I came across one of those Mideast broadcasting stations playing some eerie chanted music. Up on top of the Pyramid of the Sun about 3:00 am, it produced a most unique setting. I didn't want to be selfish, so I transmitted it on two meters for the group

Mark K. Toutjian XE1MKT works 2 meters, using Kenwood's TR-2500 handie-talkie; the Pyramid of the Moon is in the background.

down below us and just about scared them to death!

Early Sunday daylight on February 13, 1983, came around quick. It was beautiful to see the sunrise over the horizon of Teotihuacan, the City of the Gods, as I concluded my 24-hour QSO "poco a poco." I'd get to joking and even be a little silly on the air with my fellow hams around the world. "Hey! Did you hear the latest Mexican weather report? Chile today and hot tamale!"

We got to thinking about what response or reaction we would have had if ancient Teotihuacan tribes were still living there and saw us transmitting from their temple area on the high peak of their Pyramid of the Sun. (All we were lacking was a time machine manufactured by Kenwood or some other serious-minded manufacturer!) One thing for sure, we would have had no complaints of TVI! We were comforted by the thought that the Teotihuacans were not a violent, but a peaceful tribe compared with others such as the Aztecs, known for their sometimes thousands of human sacrifices each year!

I'm not Speedy Gonzales on the air. I enjoy being conversational with others. For me, that adds the fun to ham radio. I meet and get to know different ones who become real friends, and I have enjoyed long-lasting friendships over the air from all over the world. That's the name of the game for me. I do it just for the fun of it.

We finally left our fine abode on the Teotihuacan Peak, and I'll never forget that hot cup of coffee that awaited me down below or that last celebration, ended by saying adios to our amigos at the famous City of the Gods.

Future DXpeditions may await us here in Mexico, since the country itself is full of original sites such as the famous volcano, Popocatepetl, or Silent Valley, Durango (where astronomical expeditions are held). Mexico is a country with a wide variety of beautiful and unusual settings for field days or technical operations for amateurs. Come on down whenever you wish! Organize a DXpedition as we do—just for the fun of it!

THE NETHERLANDS

Henk Meerman
Zandvoorterweg 33
2111GR Aerdenhout
The Netherlands

Sponsored by many local hams, a brand new repeater for two meters is now on the air in the Netherlands. In a small country like ours, a new repeater is quite an event.

The repeater, homemade by Ari Bol PAØQHN, operates on 145.775. The machine is now located on top of an old water tower near Heemstede, and it covers the midwest area of Holland; its callsign is PI3HLM. Now almost the whole country is covered by VHF repeaters, with a total of 19!

The club station PI4HLM of the NCV (a Dutch radio society) will be on the air this year on the 29th and 30th of October, on all bands. Maybe a good tip for special prefix hunters.

In our country of wind and water, it is easier to get a ticket for amateur radio than one for operating one of those old windmills we have. We have four license categories: A, B, C, and D. The easiest way of getting involved is to pass an exam for a D license. It requires only a basic technical knowledge and no code. With a D license, you are allowed to operate a 15-Watt FM rig from 144.9875 to 145.800 MHz.

The next step you can make is to get a C license; it takes a little more technical knowledge but still no code. When you pass this exam, you are able to operate on all bands above 144 MHz in all modes and with a power output of 30 Watts. Due to the introduction of the D license, the two-meter band is very popular in Holland.

Most of the Dutch hams use Japanese rigs, but there are also many guys who work with homemade equipment or converted ex-army and surplus machines.

In Holland, there are three major amateur radio societies: VERON, which is the Dutch section of the IARU, PO Box 1166, 6801 BD, Arnhem, The Netherlands; VRZA, at PO Box 61420, 2506 AK, The Hague, The Netherlands; and NCV, PO Box 2999, 2002 RZ, Haarlem, The Netherlands.

The VERON also has a special club for female hams called the Dutch YL Club. It is there to encourage women to get involved in the hobby, keep contacts with other YLs around the globe, and join in to organize special contests. Address the DYLC at Ir Lelylaan 69, 2103 HN, Heemstede, Holland.

So, if you have any questions, or something you would like to know about amateur radio in Holland, you can write to them. (Don't forget an IRC for return postage.)

NORWAY

Bjorn-Hugo Ark LA5YJ
Postboks 39, Manglerud
Enebakkveien 208
Oslo 6, Norway

REVISED RULES FOR WALA

"Norges-sertifikatet"—Worked All LA—is available to licensed radio amateurs and SWLs all over the world. Contacts with LA and LB stations made after January 1, 1950, are valid for the award. The required number of contacts must be worked from the same QTH, within a radius of 100 km.

Requirements for HF: Applicants in Denmark, Finland, Faeroe Islands, Iceland, Sweden, and Norway must produce evidence of two contacts on separate bands with each of the 19 counties (fylker) of Norway. Applicants in the rest of the world must produce evidence of one contact with each of the 19 counties on any band.

Requirements for VHF/UHF/SHF: Applicants in Denmark, Finland, Sweden, and Norway must produce evidence of contacts with at least 16 of the 19 counties. Other applicants must produce evidence of contacts with at least 12 of the 19 counties in Norway. Contacts via repeater or satellite are not valid.

Contacts may be made on all legal modes. Crossband contacts are not allowed. WALA may be endorsed as appropriate. Contacts with arctic stations (JW or JX) count for the award. Such contacts may substitute county W, X, or Y.

The counties of Norway are A—Oslo, B—Østfold, C—Akershus, D—Hedmark, E—Oppland, F—Buskerud, Z—Vestfold, H—Telemark, I—Aust-Agder, K—Vest-Agder, L—Rogaland, R—Hordaland, S—Sogn og Fjordane, T—Møre og Romsdal, U—Sør-Trøndelag, V—Nord-Trøndelag, W—Nordland, X—Troms, Y—Finnmark, JW—Svalbard/Bear Island, and JX—Jan Mayen.

The application shall include a list of the stations worked and must be accompanied by QSL cards or the following information extracted from the QSL cards and verified by an officer of the applicant's national radio amateur society: date and time UTC, callsign, signal reports, and QTH of the station worked. Other relevant information may be necessary if endorsements are required.

The fee is N.kr. 20 or 10 IRCs and applications may be sent to the Norwegian Radio Relay League, PO Box 21 Refstad, Oslo 5, Norway, or to the NRRL Award Manager, Erik Jahnsen LA7AJ, Kaupangruta 21, N-3250 Larvik, Norway. Applications will be accepted until December 31, 1983.

DIPLOMA HUNTERS

Last month was about DX and reciprocal licensing, but what about Norway itself for those not too interested in DXing directly? Is there anything to gain for the diploma hunter? Yes, indeed there is. One is WALA, described above. Absolutely the same as Worked All States, WAS, from Norway (maybe a little harder, since there are only 4000 amateurs in Norway). This one could be something for the diploma hunter looking for a real "goodie." Then when you have accomplished the difficult job of working them all, try for an 80-meter endorsement—or what about 5 bands? You surely will have some great times ahead of you.

Where do I find LA stations, you may ask. Well, 20 meters is a good place to start. Around 14.325-.300 MHz, you will hear the Norwegian MM net. Many LAs check in there. SAC, the Scandinavian Activity Contest, is one. By the way, the LAMM net is usually active in the late evenings UTC, or between 2000 to 2400. 40 meters early morning UTC is another good time, and of course I am sure many of the LA boys will be happy to give a call on 2 meters to give you a hand with a couple more counties. Have a good time, and good luck.

PAPUA NEW GUINEA

Siegi Freymadl P29NSF
PO Box 165
Rabaul, Papau New Guinea

In Papua New Guinea, amateur radio licensing is handled by the Radio Branch of the Post and Telecommunication Corporation. The postal address is PO Box 3783, Port Moresby, National Capital District, PNG. The matter of reciprocal licenses is at present being sorted out. PNG has reciprocal agreements with member countries of the Commonwealth as well as Switzerland and the United States of America, but Japan, France, and the Federal Republic of Germany have not replied to approaches from PNG. Singapore has advised that individual applications will be considered.

Visiting amateurs from these countries will receive a permit to operate in PNG upon presentation of a photocopy of entry visa, photocopy of the relevant page in the passport giving details for identification purposes, and a photocopy of the amateur operator's certificate and current license. A resume giving details of residence and employment over the past 10 years is also required of the applicant. If a visiting amateur presents himself at the Radio Branch with all this information, he will be able to walk away with a permit to operate.

Amateurs who are coming to Papua New Guinea to take up employment are required to submit the same information as visitors. They will then be given permission to operate and a license will be issued after about one month.

As far as maritime mobile operation is concerned, the situation is that when a yacht enters PNG waters it is allowed to operate MM P29, following written application.

While PNG honors licenses obtained in the USA, the reverse does not apply. It appears that an agreement at an intergovernmental level is needed.

The minimum age for an amateur to be granted a license in P29 is fourteen.

News has been received from Keith P29QA at Arawa, Bougainville Island, that 6m activity was very good during April, when he contacted a number of Japanese stations. Bob P29NBF can at times be heard operating aeronautical mobile at 35,000 feet from his company's new 11-seat jet.

Probably a great deal has already been written about the ill-fated Spratly Island DXpedition. However, as I became involved also, I feel that I should set down my experiences.

On 16 April from approximately 1000 GMT, I began to operate on 15m beaming towards Europe, as I frequently do. Signals were excellent and the response very good. At that time, I was blissfully unaware of the Spratly Island DXpedition or any of the events surrounding it.

At 1028 GMT, I was called by a station giving a UKØ callsign who then informed me that a Russian ship had rescued four persons from a boat and that these people had been placed in a hospital in Siberia and were receiving medical treatment. He added that he could not give either the names of the people or the name of the yacht for security reasons. He requested that I pass this information on to the MM Net on 20m. I repeat once more that I then had no idea of the happenings in the South China Sea.

As my license does not permit me to operate on 20m, I was going to ask either Shirley P29SM or Phil P29PM, who were staying with us at the time, to pass on the information. However, before I could do this I was called by Phil VS6CT, who told me to disregard the message as the OM who had passed it on was a well-known pirate who was in the habit of spreading bogus messages. I left it at that and continued to work European DX, but the UKØ station kept on interrupting and repeating the already-mentioned information. Finally, he became very abusive towards VS6CT, and as I was not willing to put up with this sort of QRM any further, I went QRT, not a little bemused.

The following morning, our Sunday (2352 GMT Saturday), I was talking to some of my Australian friends when I was again called by Phil VS6CT. Phil then filled me in on all the events regarding the Spratly Island DXpedition and the yacht *Sidharta* up to that date, as they were known to him. VS6CT and NØZO/DU2 and a number of other stations had maintained contact with the yacht up to its disappearance and since then had kept a round-the-clock watch on the amateur bands, hoping to pick up signals from the *Sidharta*.

The last transmission received had been at 0652 GMT of April 10 on 14.320 MHz, and it was "fire on board." Phil, who was on vacation and due to start an overseas trip, spent most of his days monitoring the bands for a signal from the yacht. He and other amateurs were plagued by bogus distress messages, and a great deal of effort and money had been expended in following up the information while the fate of the yacht and survivors remained unknown. Phil also mentioned

that the OM who had used the UK0 callsign the previous evening had also been known to use a YB callsign. He is easily identified because of his gravelly voice.

Following this QSO, I called in on the VK4 WIA talk-back, passing on details of the events and the callsigns used by the pirate.

About a week or so later I heard that four survivors had been picked up by the Panamanian freighter *Linden* which was on its way from Singapore to Hong Kong. The *Linden* picked up the survivors from the *Sidharta* who had taken to their life raft after being fired at on April 10. One of their group was killed instantly and one was wounded and died some days later in the raft. He was buried at sea. They had been adrift for nine days when the *Linden* sighted them near Amboyna Cay of the Spratly Group of Islands.

Therefore, the information given to me on April 16 by the pirate was a hoax and in very bad taste. This and the bogus CW distress signals caused a lot of people a lot of work and expense, all to no avail. One wonders what could motivate anyone to stoop so low as to deliberately spread false information.

See you next month!

VERIFICATION

On the memorable day of December 13, 1981, use of amateur radio equipment in Poland was forbidden. Possessors of transmitters and sending-receiving devices were obligated to place their equipment on deposit in 48 hours, and their licenses became void. Polish hams ceased to modulate the ether with their signals.

After martial law went into force, other activities of the organization uniting Polish radio amateurs—Polish Radio Amateurs Association (PRAA)—did not cease. The Technical Commission of PRAA began to develop plans for modernizing the equipment used by Polish hams.

A harbinger of a change for this long-lasting hush in the ether came flying on October 23, 1982. On that day, the meeting of the Presidium of PRAA took place in Warsaw. The first action undertaken brought up to date all suspended licenses. As a first step, the main Verification Board at PRAA was called into being. After the meeting of the Presidium of PRAA with presidents of district departments of PRAA, held in Warsaw on November 8, 1982, District Verification Boards at PRAA were in the making. It was decided to enter upon the subject outright. But . . . one swallow doesn't make a summer.

Every member of PRAA—there are no radio amateurs in Poland who do not belong to PRAA—who would like to have his license brought up to date was to complete a letter of application filling out printed forms in duplicate, edited by PRAA. An applicant was to bring to light details of his former activity in PRAA, command of foreign languages, membership in organizations, and so on.

Letters of application would be assessed by the local club of an applicant. Completed forms would be handed over to the District Verification Boards that once more would pass their opinions. District Verification Boards then would turn them over to a District Inspectorate of State Radio Surveillance.

The presence of applicants at meetings of District Verification Boards will not be necessary. In some cases the board may demand logbooks of radio stations or received QSL cards as evidence of previous activity. License updating will last to the end of 1983. Those who don't submit before the day of expiration and want to regain licenses must apply in compliance with obligatory rules, as if they were applying for the first time.

The first sitting of the main Verification Board took place in Warsaw on November 23, 1982. It was there announced that District Inspectorates of State Radio Surveillance will receive instructions relative to investigations of applications. It was decided to first investigate applications of the members of the Head Radio Board—a new body in PRAA that will take care of complying with the rules binding radio amateurs. Their District Verification Boards have begun their work in most districts of Poland.

All Polish radio amateurs are waiting for the moment when the Polish sky will sound with their callsigns and they will be able to establish contacts with their old friends.

THAILAND

Tony Waltham HS1AMH
c/o Bangkok Post *Newspaper*
968 Rama IV Road
Bangkok 10500
Thailand

The latest issue of the international *Callbook* testifies to the popularity of amateur radio in Thailand, with some 510 radio amateurs listed and the number growing all the time. But what the *Callbook* listing does not demonstrate is the vast upsurge in interest in radio as a hobby, largely due to a pilot project begun two years ago by Thailand's Post and Telegraph Department.

It was then that the PTD began what it regards as a forerunner for full amateur radio licenses on a broad basis by granting permission for Thais who have passed a written test to own VHF transceivers and operate on spot frequencies in the two-meter band. HS callsigns were *not* granted, however, and the operators received a number, preceded by the letters VR, standing for volunteer radio operator.

Many of these VR operators—who now number over 600, along with a waiting list of others who have passd the test—also hold the HS callsigns found in the *Callbook*, and some are well-known operators internationally.

Thus there are a large number of Thai radio-hobby enthusiasts who can be met, in Thailand, only on the calling frequency of 144.500 MHz—but for the time being by other Thais only, as no foreigner has yet to be granted this status.

Many ask where Thailand is on the HF map these days. Recently, Thailand used to be the only country active in Zone 26, and not a few anxious DXers are seeking a contact with Thailand while Burma, Laos, Cambodia, and Vietnam stay QRT for their own differing reasons.

The Thai PTD is currently reviewing the status of amateur radio, and previously-active amateurs still possess licensed HF equipment—on the condition that they do not operate unless granted special permission for the time being. For those eager for an HS contact, the best suggestion was to listen out during the JARL-organized All-Asia DX contest in June or during the SEANET (Southeast Asia Net) contest which was to be in August. The station was to be signing HS0HS, and probably chalked up close to 3,000 contacts if past performance is any indication.

Last November's SEANET Convention was hosted by the Radio Amateur Society of Thailand (RAST) in Bangkok, and some 100 hams from overseas attended to hear several eminent speakers, including ARRL Vice President Carl Smith and *73*'s very own Wayne Green. Events included a trip out to the VOA one-megawatt medium-wave transmitting facility just north of Bangkok, as well as the usual eyeballing and display of equipment.

Next year's event will be held in Singapore from November 18 to November 20, and those seeking further info can write to the Singapore Amateur Radio Transmitting Society or, propagation willing, tune in to 14.320 MHz daily, the Southeast Asia Net frequency. The net begins at 1200 UTC with net control usually in BK2, VS5, VS6, or 9V1. It is not a DX net, but any station desiring to contact a check-in may call "contact" and the NCS will assign them both a clear frequency as standard net procedure.

WARC BEAM ANTENNAS

The Federal Republic of Germany was one of the first countries where radio amateurs were allowed to operate on the new 10-, 18-, and 25-MHz bands. Foreseeing this development, antenna designers in this country were at their drawing boards right after WARC '79. First designs for new beam antennas were presented in 1980. After some refinements, production began in 1982. It is interesting to see what is available today and how to plan ahead regarding antennas in those places where the new bands are yet to be opened.

One manufacturer, the Kurt Fritzel Company (Sonnenwendstr. 41, 6702 Bad Duerkheim), offers a whole range of trap-beam antennas. Let's look at some of the design principles and their implementation. They decided initially that the size of the largest beam should be 11 × 7.5 meters. This corresponds to the size of a 3-element monobander for 20 meters, which constitutes an upper limit for the average ham regarding installation, maneuverability, and appearance of the antenna. However, in the course of the optimization process, they ended up with a boom length of up to 10 meters. Such a length was needed for their largest antenna, a 7-element/6-band beam. They also decided to interlace two 3-element beams for 10/18/25 MHz and 14/21/28 MHz, each with its own coax feedline, in order to achieve 6-band performance. Conventional 3-element trap-beams with a boom length of approximately 5 meters thus can be upgraded by interlacing it with a new 10/18/25-MHz beam. Calculations showed that a 6-band trap-beam with only a single feedline would have required 10 traps for the radiator, which could not be accommodated mechanically.

Four types of beam antennas are illustrated here as examples to demonstrate essential features of their respective class. Fig. 1 is the conventional 3-element/3-band design adapted for the new bands on 10/18/25 MHz. With a boom length of 7.5 meters and a length of the longest element of 10.3 meters, the UFB 33 beam covers an area of 77 square meters—twice as large as the conventional beam. Three elements are active on each band and a gain of 7/8/6 dB compared to a dipole is claimed. The price of 872 DM (US$350) is about 25% higher than for the conventional 3-element/3-band beam.

For only 93 DM (US$38) more, a 4-element/6-band beam for 10/14/18/21/25/28 MHz is offered with the same length of the longest element and the boom length reduced to 5 meters (Fig. 2). The peculiarity of the FB-DX 460 beam is that it has 3 active elements on the conventional bands but only one active element on the new bands. Hence, a gain of 0/7/0/8/0/7 dB compared to a dipole is claimed. However, this antenna gives

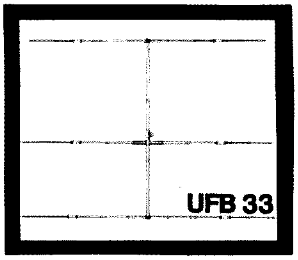

Fig. 1.

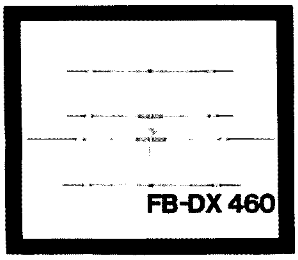

Fig. 2.

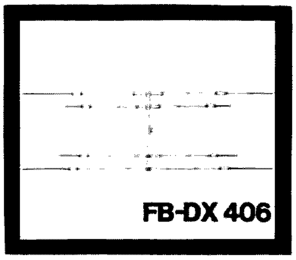

Fig. 3.

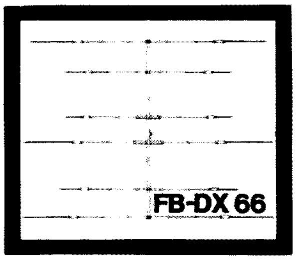

Fig. 4.

6-band performance, is not much larger, and with a price of 965 DM (US$386) is "only" 40% more expensive than a conventional 3-element/3-band beam.

It is surprising to note that for almost the same amount of money, a 4-element/6-band beam (FB-DX 406), with longest element/boom dimensions identical to the FB-DX 460, is available. However, this antenna has 2 active elements on each band and offers a gain of 5/5/4.5/4.5/4/4 dB on the 6 bands when compared with a dipole (Fig. 3).

A typical representative of the upper class—6-band performance comparable to the conventional 3-element/3-band beam—is the FB-DX 66 (Fig. 4). With a length of the longest element of 10.3 meters, a boom length of 6.75 meters, 5 active elements on 18/25 MHz, and 3 active elements on all other bands, it offers a gain of 6/6/9/7/9/8 dB on 10/14/18/21/25/28 MHz compared with a dipole. But with a price tag of 1590 DM (US$636), it is more than twice as expensive as the conventional 3-element/3-band beam and costs as much as two separate beams for 14/21/28 MHz and 10/18/25 MHz. But remember, interlacing of the existing 3-element/3-band beam for 14/21/28 MHz with a new beam for 10/18/25 MHz, e.g., the UFB 33, may be possible in order to achieve the same performance at half the price.

Other characteristics of the UFB 33/FB-DX 460/FB-DX 406/FB-DX 66 antennas are: turning radius, 6.5/5.2/5.7/6.5 meters; weight, 23/22/23/38 kilograms; and wind load at 135 km/h, 670/810/840/1200 Newtons.

Trapless beams with up-to-7-band performance (including 40m) are offered by another German manufacturer (W. A. Sommer, Kandelstr. 35, 7809 Denzlingen). But the few examples discussed here illustrate quite well some basic alternatives which are available today for the average ham. And now, what can be expected in the future from the US, Japan, and other parts of the world?

SSA ANNUAL MEETING

Sundsvalls Radioamatorer, Club SK3BG, hosted this year's annual meeting of the national league, Sveriges Sandareamatorer (SSA), on the last weekend in April.

This was an opportunity for the members to get together, meet their representatives in the league, and express their opinions at the meeting. Also, of course, the major dealers in ham equipment were exhibiting and selling their goodies, and the Saturday night dinner dance is a nice way of getting to know each other better.

Sundsvall Radioclub had arranged everything under one roof. It was a pleasure to enter the hotel room and to find beautiful flowers, chocolate, and refreshments as a gesture of welcome from the club. Sunday is reserved for the meeting that usually ends by early afternoon, after which many must drive several hours to get home.

Saturday, however, is a busy day for everybody. This is the opportunity to get an eyeball QSO with an old-time friend with whom you have talked over the radio for years but never met personally.

Sundsvall should be well-known to every active DXer. It is the home town of Erik SM0AGD, a member of the DX Hall of Fame. Sundsvall DX Group handles his QSLing and they also do their own DXpeditioning, of which the most recent is the J5AG operation from Guinea-Bissau in Africa. Leif SM3RL, one of the members of the expedition, gave a most interesting talk on their experiences and showed us beautiful slides from the trip. Unfortunately, Erik SM0AGD could not attend because he was on his way to US and the Dayton Hamvention.

The hosts had put together an amazingly well-filled program. The VHF/UHF forum was about the Phase III satellite program. Gudmund SM2BYA talked about the Swedish ionosphere research. Talks were also held about antennas and baluns, as well as fox-hunting and AMSAT. Ulf SM6CVE exhibited his valuable radio stamp collection.

No major controversial matters are under discussion amongst Swedish hams for the time being, but two motions were about the planned change within IARU Region 1 for channel separation on the 2-meter FM band from 25 kHz to 12.5 kHz. With only nine repeater channels, of which two have been taken by the satellites operating on 145.800 MHz and above, this is an issue of concern amongst the fast-growing 2-meter FM population all over Europe.

SSA has a membership of about 7,000. Usually, this annual event draws about 400 members, but many more are taking part in the affairs through proxy. Election of the members of the Board is done by mail. SSA president is Bo Lindberg SM0HDP, and the secretary is Stig Johansson SM0CWC. Every one of the eight call areas has one representative elected by the members in that area.

WSRA AWARD

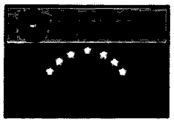
How about getting an award from another of the capitals of the world? Stockholm Radioamateurs (SRA), SK0AR, issues the Worked Stockholm Radio Amateurs Award. The rules are:

1. Any licensed radio amateur can apply for the WSRA award.
2. Two-way contacts with SRA members required as follows: Swedish hams—10 different SRA members; all others—6 different SRA members.
3. The contacts shall be on phone, CW, mixed.
4. All amateur bands can be used.
5. Crossband contacts do not count.
6. All contacts have to be made from the same call area with the same callsign.
7. Contacts made after January 1, 1960, are valid.
8. Send your listing of QSL cards received (but do not send the cards) to WSRA Award Manager, Olle Engdahl SM0IEA, Morbydalen 1, 8 tr., S-182 32 Danderyd, Sweden.
9. Please have the QSL listing verified by two licensed hams and enclose either Sw. crowns 15.–, US$3.00, or 8 IRCs with the application.

SCANDINAVIAN ACTIVITY CONTEST

The SAC is sponsored by the four Scandinavian leagues with responsibility rotating so that each club has the job with the contest logs every fourth year. The contest takes place the two last weekends in September; in 1983, CW on September 17-18 and phone, September 24-25.

This is one of the contests that follow the IARU recommendation for national contests not to cover all of the bands. That is the reason why you in the SAC should leave the lower and higher portions of each band free from contest operation so non-contesters can chew the rag somewhere. The details for the contest are usually published in contest columns. See you in the Scandinavian Activity Contest in September.



VENEZUELA

Luis E. Suarez OA4KO/YV5
Apartado 66994
Caracas 1061-A
Venezuela

Foreign correspondent!! Can you imagine that? It was exciting to receive the offer from *73*'s technical editor, Avery Jenkins WB8JLG. Back home from the mail office, I shouted the news from my home's door. My wife and daughters said almost at once: "You must accept it!" I accepted, and here I am, as a foreign correspondent for *73* in Venezuela.

I'm Peruvian and have been living in this beautiful country for around ten years. I live with my wife Olga and two daughters, Barby, 13, and Susy, 12. I'm a communications consultant and have been a licensed amateur since 1959. As per Venezuelan communications regulations, I'm OA4KO/YV5.

I have talked about me, and now let me talk about the country where I live. Venezuela is one of the eleven independent countries on the South American continent. It was a Spanish colonial possession until April 19, 1810. The national territory is located at the north of South America between the Caribbean Sea, Brazil, Colombia, and the Republic of Guyana. The coordinates at mid-country are 8°48" North and 67° West. So you know roughly where to beam your antenna while listening to a YV. In the accompanying table, I have listed more accurate coordinates. The surface area is 912,050 square kilometers (1/8 the US territory and twice that of France). The population is 14,500,000. There are around 16,000 licensed amateurs and a zillion CBers, both licensed and pirates.

A federal constitution sets forth 20 states, a federal district, two federal territories and 72 islands. Each state has a governor designated by the president and a legislature. There is a federal government with executive, legislative, and judicial branches. The president is elected for a 5-year period, but he cannot be reelected before an elapse of two presidential periods.

The official language is Spanish. There is freedom of religion but most people profess to be Roman Catholics. The people here like baseball, boxing, basketball, and football (soccer), in that order. So, from a sports point of view, we like the same athletic activities as people in the USA. Many Venezuelans are baseball players in the USA and many are well-known in Japan, too. Most baseball games from the US are retransmitted by local TV, and the most important of both the National and the American League games are directly transmitted. Needless to say, the World Series is also transmitted directly. But don't think that baseball is the first sport in South America. No, sir, football (soccer) is number one in all SA countries except Venezuela.

For radio communications purposes, the country is divided into the ten call areas (circuitos) shown in Table 1.

I will write in following columns about requirements for licensing, reciprocity, VHF repeaters, radio clubs, awards, contests, satellite activities, EME, etc., and also include some news about YV6 (Isla de Aves) for all those DX chasers. Furthermore, some paragraphs regarding this country will always be included to let you know more about Venezuela.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

Sacramento CA

TOWERS—galvanized steel stack/crankup and accessories. Northern California factory direct to you. California Antenna Systems, 6020 Windy Ridge Road, Shingle Springs CA 95682, 677-9540.

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Azden, AEA, Kantronics, Santec. Full Line of Accessories. No Sales Tax in Delaware. One mile off I-95. Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.

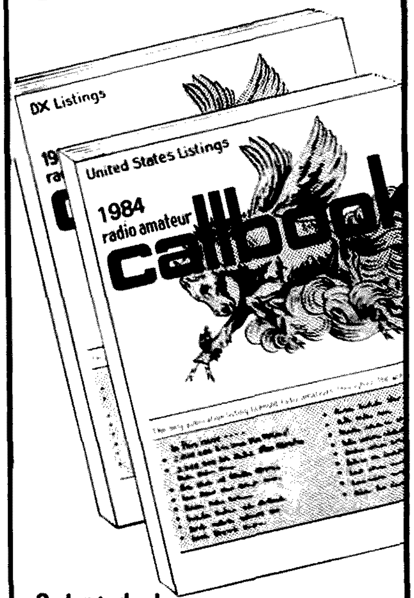
1984 CALLBOOKS



Order today!
NEW 1994
RADIO AMATEUR CALLBOOKS
READY DECEMBER 1st!

Known throughout the world for accuracy, the 1984 Callbooks are a better value than ever before. The U.S. Callbook contains over 430,000 listings; the Foreign Callbook has over 400,000. More than 75,000 changes have been made in each edition since last year. Special features include call changes, Silent Keys, census of amateur licenses, world-wide QSL bureaus, International postal rates, prefixes of the world, and much more. You can't beat this value! Order your 1984 Callbooks now for earliest delivery.

	Each	Shipping	Total
◻ U.S. Callbook	$19.95	$3.05	$23.00
◻ Foreign Callbook	18.95	3.05	22.00

Order both books at the same time for $41.95 including shipping within the USA.

Order from your dealer or directly from the publisher. Foreign residents add $4.55 for shipping. Illinois residents add 5% sales tax.

Keep your 1984 Callbooks up to date. The U.S. and Foreign Supplements contain all activity for the previous three months including new licenses. Available from the publisher in sets of three (March 1, June 1, and September 1) for only $12.00 per set including shipping. Specify U.S. or Foreign Supplements when ordering. Illinois residents add 5% sales tax. Offer void after November 1, 1984.

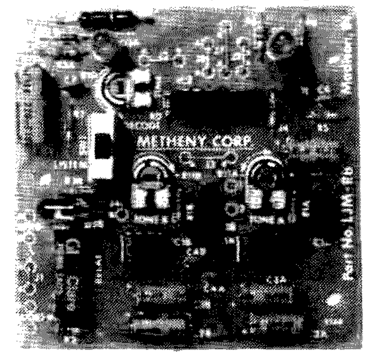
$15 DTMF DECODER $15

The LJM2RK decoder kit converts your receiver into a special receiver or control. When a user-selected time-tone combination is received, the output provides a relay control for activating speakers or other devices.

INPUT: Audio from transceiver, scanner, etc.
OUTPUT: SPST (N.O.) relay.

FEATURES: Single or dual tones adjustable over the 16 digit Touch Tone range • Adjustable response time • Relay output • Manual or auto reset • Single tone ON latching with different single tone reset OFF • Operates on 12VDC • Interfacing of multiple boards for multi-digit sequential activation and reset.

APPLICATIONS: Call-up system • Repeater or commercial controls • Etc. limited only to your imagination •



Actual Size 3"x3" - Shown Assembled

LJM2RK decoder kit includes all component, relay, and P.C. Board. . . . $15 plus $1.50 shipping.

LJM2RC enclosure kit includes molded case, speaker, input cable. . . . $5 plus $1.50 shipping.

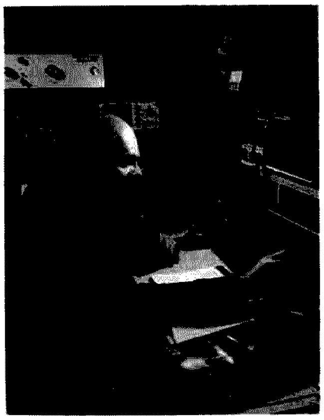
NEVER SAY DIE
editorial by Wayne Green



INSTANT GENIUS

Fast quiz: Which is the third largest consumer magazine in America? You may be surprised as I was to learn that *Folio*, the publishing magazine, has announced that *80 Micro* was in third place last year. Not bad for a magazine just two years old.

Vogue was second and *Byte* was in first place. So who conceived of and started two out of three of the largest consumer magazines in America? Yep! We're talking about me...the chap the League has been reviling for years.

Both magazines were original concepts. *Byte* was the first magazine about microcomputers and *80 Micro* was the first magazine devoted to a specific computer system. Both magazines have generated dozens of imitators. Now I have an idea for another completely new type of magazine, one which could be as successful as *Byte* and *80 Micro*. We'll be getting started with it as soon as I can find some people to help.

Just as *Byte* was a powerful force in helping the microcomputer field to grow, *80 Micro* has made it possible for hundreds of small firms to get started in support of the TRS-80 and grow to multi-million-dollar size. My predictions of eight years ago have come true: We've seen more new millionaires in the last few years than ever before in history...all because of microcomputers. And we really haven't seen anything yet.

The recent sale of my publishing firm to the *Computerworld* group for $60 million has generated some respect in ham circles. The gadfly and eccentric now gets listened to a little more attentively. Fine, for I have a message which should be heard. It's one I've been preaching for many, many years.

At the Atlanta hamfest in 1976, I remember trying to convince a small group of sullen hams that if they wanted to, they too could make any amount of money they desired. I pointed out that the microcomputer industry was just starting and that there was an unlimited potential for getting rich if they would only make the effort.

On the bright side, I've had letters from several hundred people who have read my editorials or listened to me talk, have followed my advice, and have become wealthy. That's not enough; I want to see thousands of millionaires, not just hundreds.

I was about 32 when I made my first million. I didn't protect myself against an unscrupulous partner, so first he screwed me out of my share of the firm and then, not knowing how to run the business, he bankrupted it. I was the real winner because I learned how to make money... he only learned how to lose it.

In 1964, I wrote a little booklet, *How To Make A Million*. I found that the America of the 60s was not the place to sell such a book. The kids then were more interested in dropping out and in drugs than in making money. I rewrote and expanded the book during a dull day in Khartoum in 1966, while on an around-the-world trip. One of these days I'll dust off and update the manuscript. The blueprint for getting rich in the book is as valid as ever.

In 1975, with the starting of *Byte*, I again got into the millionaire class, only to see it disappear one night...again lost because of my trusting someone.

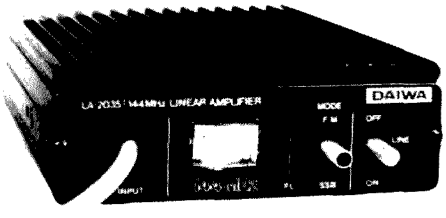
CROSS NEEDLE METER
DAIWA

BE HEARD! GIVE YOUR HAND-HELD THE BOOST IT NEEDS!

The New Daiwa LA-2035 two meter linear amplifier.
A compact amp at a compact price
Only $79.95 Suggested Retail.

This amplifier is designed for use with hand-held transceivers in either mobile or fixed station configurations.
Because of its light weight and compact size, the LA-2035 can be mounted under the dash, under the seat, or in any other convenient location.
The LA-2035 is equipped with RF activated stand by circuitry.
Easy operation. Simply connect your antenna and your hand-held to the LA-2035. Connect the LA-2035 to a suitable power supply and go.



Specifications
Band: 144-148 MHz
Mode: FM/CW/SSB
Input power: 1-3 watts
Maximum output power: 30 watts plus
Power consumption: 13.8VDC at 5A Max
Dimensions: 100W × 35H × 125Dm/m
Weight: 500 grams
Coaxial input cable supplied with a BNC connector.
Output connector: SO239

QSL OF THE MONTH

From high tech to soft tech is the theme of this month's winning QSL card. Ohio's Michael Bryce WB8VGE has taken advantage of the freebies given to us by Mother Nature and used them to power his station. The card depicts a solar panel and a wind generator, Michael's two sources of energy. So when you hear WB8VGE say he is just shooting the breeze, you better believe it.

If you think your QSL card is a winner, put it in an envelope with your choice of a book from *73's* Radio Bookshop and mail it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not in envelopes or without a book choice will not be considered.

So, grumbling a lot, I started in again.

Now my goal is a billion. Oh, that's more of a side goal, since money has never been important for me. My real goal has been to provide education and entertainment for as many people as possible. But to do that I have to make money, so that goal has been inescapable.

A billion? Sure! And one thing is certain: To reach that goal, I'll help make several thousand millionaires along the way. The secret is simple: Figure out what is coming up next in technology, run quickly to the front of the parade, and then try to lead it.

For instance, I see the time not far ahead when education is going to be a marketable product. To get ready to take advantage of that concept, I'm now in the process of starting a college. This will escalate into an educational cable television network. The last step is interactive education on video disk which can be sold anywhere in the world. That's where most of my $60 million is going to be invested.

Since I feel that amateur radio is a key element in bootstrapping our country into technology, I'm going to be working hard to see that amateur radio gets into a strong growth pattern. Old-time hams who would prefer to see fewer hams and thus less interference on the bands are going to have a fight on their hands since I'm aiming for two million licensed hams by 1990.

Interference? Poo. With high-speed digital technology, we'll have far less interference than we do today. Indeed, I think we can develop some communications techniques which will be error-free and virtually instantaneous anywhere in the world.

One of the bonuses of success is that it is a lot easier to be heard. The incentive licensing debacle of 1963 kept me and *73* impoverished as the growth of amateur radio stopped for ten years. The disaster threw virtually every ham manufacturer out of business. If *73* had been stronger, I might have had the muscle to stop the debacle instead of just reducing its impact.

You've read about the FCC's Long-Range Planning Committee. The goal of this group is to help develop an emergency communications system for America which will be capable of surviving even an atomic attack. I think this can be done...and that amateur radio can do it. But I'm not talking about a handful of HTs and some surviving repeaters or 80-meter traffic nets using Morse code.

Several years ago, I pointed out in an editorial that a dependable emergency communications system would be a powerful deterrent to nuclear attack. Reagan has said the same thing recently, which sort of puts the ball in our court. Right?

Six Antennas from Three Wires

With these modified Beverage antennas, you double your directions without doubling your cost.

"Oh my, he's weak. Egads, what static. Oh well, let's turn the beam and see where he peaks up."

Sounds like a natural enough sequence, doesn't it? Well, at K1VR, we can do just that on *160* (and *80*, and *40*. . .) meters, and no antenna is higher than 15 feet. In fact, there is no "beam." Instead, we use three Beverage antennas, each reversible. Not bi-directional. . . reversible. This article will show you how we do it.

An Old Antenna

First described in a 1922 article by H. H. Beverage,[1] the Beverage is a receiving antenna described by one friend as an antenna that works poorly in general, but less poorly in one direction. Its principal advantages are:

- It increases your received signal-to-noise ratio (reduces QRN) for low-angle signals (i.e., DX!).
- It has a narrower beamwidth than typical 80-meter antennas. Belrose VE2CV has described the azimuthal beamwidth as 77 degrees.[2]
- It is much less susceptible to precipitation static, so that a snowstorm in February is less likely to shut down low-frequency operations.
- It is capable of excellent front-to-side performance to reject all that static coming from around the equator.
- It reduces the need for inserting attenuation to protect the solid-state front end of your receiver or transceiver.
- If you live in the Northeast, it will quiet down all that QRM generated by those very loud W3, W4, and W8 stations who insist that they have a right to the band, too. It is not unusual to see 20-25 dB front-to-back.

A Beverage is a single-wire antenna used in receiving only. It is end-fed, 1/2 to 4 wavelengths long, strung horizontally from 6 to 15 feet above ground. Many Beverages are fed at one end, left open-circuited at the other, far end, and are bi-directional in line with the wire (see Fig. 1). Adding a terminating resistor to the far end, as in Fig. 2, makes the Beverage unidirectional, but you can't switch directions. Some Beverage users use a dc relay and switch the terminating resistor in and out, but this still does not provide unidirectional performance in each direction.[4,5,6,7]

However, if you go one step further—feed both ends of a Beverage, select either feedline and terminate the other—you can indeed have two directions from a single wire. This is what we have done, not with just one wire, but three, for six directions!

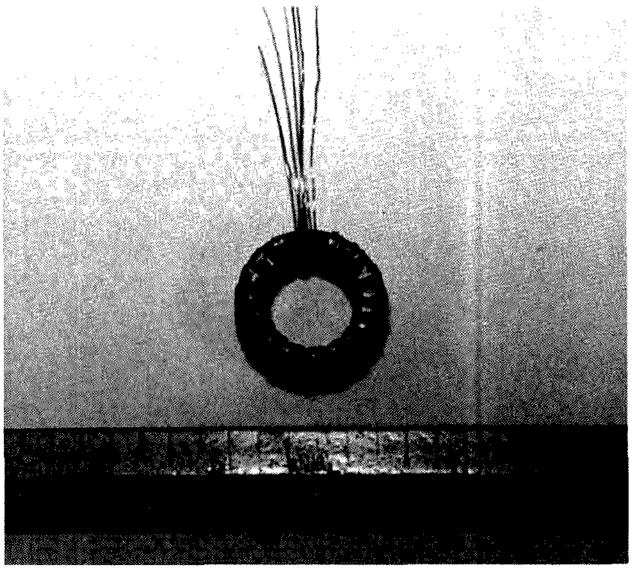

Photo A. View of toroidal matching transformer, showing method of winding.

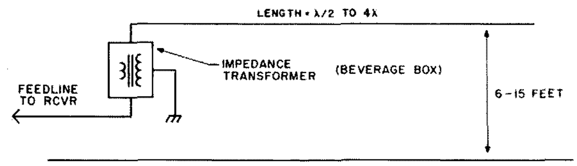

Fig. 1. A basic Beverage antenna. The directivity pattern is bi-directional along the axis of the horizontal wire. The Beverage Box contains a transformer which matches the impedance of the antenna to the impedance of the feedline.

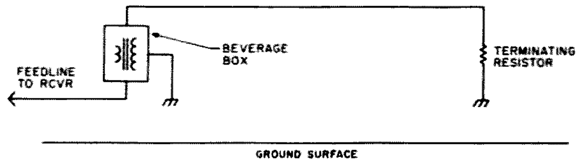

Fig. 2. A terminated Beverage is unidirectional toward the terminated end of the antenna. The resistor is a noninductive type, and experience suggests a value between 300 and 800 Ohms.

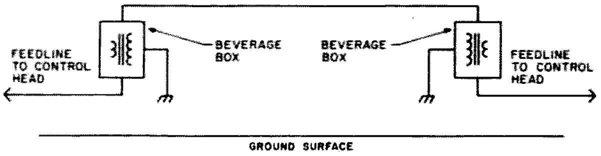

Fig. 3. The directivity pattern of the K1VR/N1RC Beverage is reversible. A control head at the operating position selects one of the two feedlines and routes it to the receiver while terminating the second feedline with a resistance. The antenna is directional toward the end with the terminated feedline. By using three such antennas and a rotary switch, six different directions can be selected.

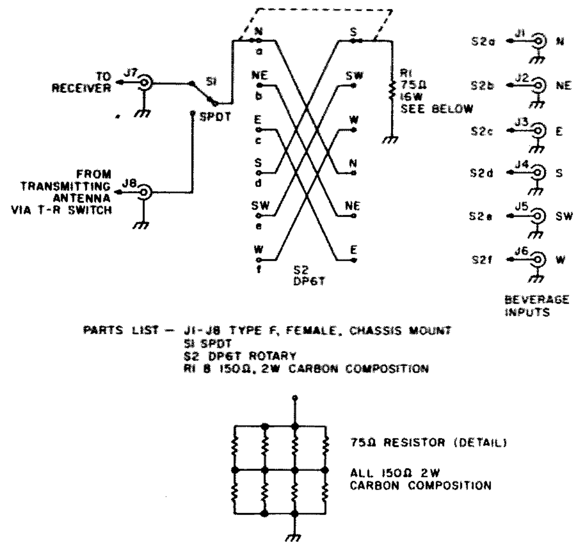

Fig. 4. Control-head schematic diagram.

A New Construction

The form of construction described in this article is desirable because few of us live on a piece of land large enough to stretch out a Beverage in each desired direction. But if you can have *one* wire, you can have *two* directions!

The system has the following components: a control head in the shack, three Beverages, six feedlines, and six "Beverage Boxes."

The control head has two switches: A Beverages/transmit antenna switch (to select the transmit antenna to listen on, if desired), and a rotary switch for selecting a favored direction.

Outdoors, we used three Beverages, which we strung between trees, but more or fewer can be used. Each end of each Beverage wire is connected through a Beverage Box to one of the feedlines. See Fig. 3. All feedlines end in the shack at the control head. Our Beverages range from 220 to 325 feet long, limited by the size of K1VR's yard.

It sounds simple because it is simple. Results: improved signal-to-noise, front-to-back, and front-to-side operation when compared with dipoles and delta loops. And you thought you couldn't rotate an 80-meter antenna!

The Control Head

In the original control head, the transmitting antenna was assigned position number 1 on the rotary switch. With a little experience, however, we soon learned that comparing reception on the Beverage to reception on the transmitting antenna was much easier with a separate toggle switch. In addition, the rotary switch had a nice even number of positions, with no empty space opposite the transmitting antenna.

The double-pole, six-throw (DP6T) rotary switch we used was the type that lets you select the number of positions desired by successively removing stops. We "crosswired" the switch as shown in Fig. 4, so that when one feedline is selected, the feedline coming from the opposite end of the same Beverage is connected to the 75-Ohm terminating resistor. Thus, if we select, say, the northeast end of Beverage A, then the southwest end of Beverage A is terminated.

Pay close attention to the wiring and labelling, or you will surely have to rewire several times, as we did, to make the switch go nicely around the compass, terminating the other end of the direction selected.

In locating the control head at the operating position, remember that while you may change bands only two or three times per hour at most, you will change directions for receiving repeatedly. So choose a location near the transceiver dial or antenna rotator, to be used by the hand you do *not* write with. The control head should also be plainly visible, so that you won't strain to hear someone only because you've forgotten to "point" the right antenna at him (or her!).

We used F connectors because they are cheap, readily available, take up much less back panel space than UHF connectors, and are much, much easier to install (a single 5/8" hole)! BNC connectors would also be appropriate. But note it is a good idea not to use a connector which may also be used in a transmitting application in your shack. Remember, Beverage antennas are for receiving only!

Finally, as we got around to attaching feedlines, it became apparent that as soon as they were identified, it was important to label them with Brady markers, tie-wrap tabs, or even masking tape to indicate direction. Without marking, eight identical RG-59 ends with F connectors quickly became confusing.

The jumper connecting the control head to the transceiver at K1VR was RG-59 with an F connector on one end and an RCA phono plug on the other. This was due to the need for RCA plugs in the Kenwood TS-520, 820, 830 series. Note that a small modification may be necessary to your transceiver to permit operation with a separate receiving antenna while maintaining the flexibility of switching back to the transmit antenna for receiving, if desired.

Feedline

Of course, the magic in the design of these antennas is that the feedlines are so inexpensive. With the advent of cable TV, so-called "drop cable" has become widely available at very attractive prices. This is the cable which is run from the telephone pole on the street to the home.

Drop cable comes in two sizes: RG-59 and RG-6. At 5 MHz, RG-59 has an attenuation of approximately .55 dB/100 feet; RG-6, which is more expensive, is approximately .45 dB/100 feet (source: Belden catalog). Therefore, since loss is inconsequential (the more feedline loss, the less attenuation you will have to insert to prevent front-end overload), choose the line on which you get the best deal. However, other considerations may contribute to your decision.

If you live near a strong local station or intend to operate in the multi-operator/multi-transmitter category in various contests, you may wish to consider the question of shielding. RG-59 is commonly available in 40% braid/100% foil or 60% braid/100% foil. The more ingress of signal that you expect, the more you should consider using 60% braid or even 95% braid. *In extremis*, these cables are also available with double shielding and double foil. Double-braided RG-6 is the cable of choice for direct burial installations.

In any ham station, the question of splicing wire often arises. A few words of advice are appropriate. If you have to put a cable in conduit to get out of your house and into the backyard, *never* put a splice inside the conduit. If you must splice outdoors, splicing and then putting the splice underground is bad business, as it is just too susceptible to water getting into the coax. Since this is a foam coax, the water will migrate without mercy. The coax is cheap; if you value your time at all, use unbroken runs of coax in conduit and underground!

Finally, when working with cable-TV coax, remember that the braid is generally going to be made of aluminum and will not solder. This dictates that all connectors must be either crimp-on BNC or crimp-on F. As for the crimping, it may be awkward, but be sure to borrow or buy the correct crimping tool. Merely using a pair of pliers will not do the kind of rf-tight crimp which will last.

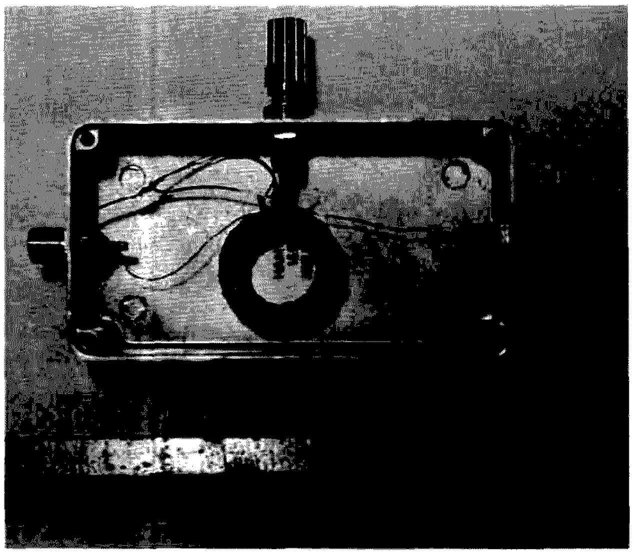

Photo B. Inside view of a Beverage Box.

Beverage Boxes (The Terminations)

The Beverage Box is the interface between one end of a Beverage antenna and its 75-Ohm transmission line. It should have minimum insertion loss, operate efficiently over a wide frequency range, and be weatherproof.

As a starting point, we knew that, according to the literature, Beverage impedances could range from 400 to 800 Ohms or so, but that we could reasonably expect an impedance in the 500–600-Ohm range.[10,11] Furthermore, we decided that rather than design a multiple-impedance matching transformer, a single 600-Ohm-to-75-Ohm design would be used. The thought of many treks into the woods to adjust taps aided in this decision!

The actual construction of the box was divided into smaller units of decision-making.

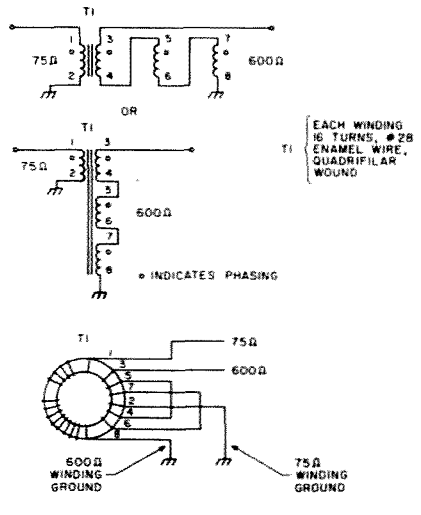

Fig. 5. Transformer winding details.

Connectors

F connectors were selected for the very same reasons we used them in the control head.

Also, watertight boots which go over F connectors are readily available. Filling them with silicone grease (not caulk) before tightening will make a very good setup. Remember to put the boot on before putting on the F connector. The authors have forgotten this rule more than once.

Binding Posts

We selected commonly-available posts and have very little to contribute to the discussion. However, it is a good idea to get the type with a hole through the post to ensure a good contact even after oxidation has begun. Also, note that some binding posts (the cheapest type) are not feedthrough types. That is, they are not insulated from the surface in which they are mounted. These should be avoided.

The Transformer

The transformer design meets the following criteria:

Impedance Ratio (Ohms)	600:75 (8:1)
Bandwidth	1.0 to 30 MHz
Insertion Loss	Negligible

The transformer was quadrifilar wound (Fig. 5), one winding serving as the 75-Ohm secondary, the other windings connected in series as the 600-Ohm primary. All windings were 16 turns, #28 enamel wire, closewound (Photo A), on an Indiana General 626-12-Q1 core (available from Permag Northeast Corp., 10 Fortune Drive, Billerica MA 01865; (617)-273-2890). Each winding had a self-impedance of 375 Ohms (5 × 75). The core of the transformer had a .75″ inner diameter, a 1.25″ outer diameter, and a .375″ width.

Note that the late Jim Lawson W2PV found that in the presence of very high rf levels—a local AM radio

28.5	37	+37

Table 1. Transformer vector-impedance measurements.

station—the toroid core saturated. He used L/C networks for transformers instead of toroids at his location.

Both a network analyzer and an rf-vector impedance meter (75-Ohm impedance) were used to verify transformer performances. Test setups are shown in Figs. 6 and 7; measurements are listed in Tables 1 and 2. Measurements made using the network analyzer are return loss as measured in decibels. "Return loss is the relation between the power returning down the line from a mismatched load to the power incident to that load." (Stephen F. Adam, "Microwave Theory and Applications," Prentice Hall, 1969.) It is related to vswr by the formula: $R1 = -20 \log_{10}(vswr - 1/vswr + 1)$. Equivalent vswr's are included in Table 2.

All measurements were made with the transformer terminated in a 600-Ohm load consisting of two 1200-Ohm, quarter-Watt, carbon composition resistors in parallel.

N1RC also tried a measurement setup which the average ham can do at home to get a rough indication of Beverage performance. Although the transformer is designed for a 600-Ohm-to-75-Ohm impedance transformation (an 8:1 ratio), it can also be used for 400-Ohm-to-50-Ohm applications. Bob made a 400-Ohm dummy load of 8–50-Ohm, 10-Watt wirewound resistors and connected it to the 600-Ohm side of the transformer. After connecting the 75-Ohm side to the "Antenna" connector of a vswr bridge and applying enough power to get a full-scale deflection, he measured the vswr (quickly!) on 160, 80, and 40 meters. It was 1.5, 2, and 3, respectively, and into a reactive load.

Winding Tips

Leave about three inches of wire free on each end of each winding. Tin each end for about 1/4"; remove the enamel by burning it off with a hot soldering iron. Wipe the tip of the iron frequently on a wet sponge to clean it. When all eight ends are tinned, identify each winding using a continuity tester or VOM. Separate out one winding as the 75-Ohm winding. Carefully solder the other three windings in series, removing excess wire (you don't need six inches), and re-tin ends before connecting the two end windings to the center windings. Pay careful attention to polarity (phasing).

Box Assembly

Each transformer is mounted in the Beverage Box on a platform built up of clear uncured RTV. When this cures, the toroid will be held securely in place. The ground ends of the windings are connected together to the ground binding post and a chassis ground. The 75-Ohm and 600-Ohm windings are connected to the F connector and input binding post, respectively. See Photo B. Be careful not to reverse these connections as we did in one box. If you need to identify windings, disconnect the ground ends from ground and from each other. The 600-Ohm winding will then show continuity from the "hot" end to the connections between its center winding and outer windings.

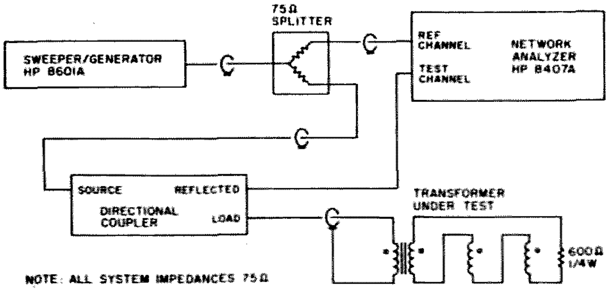

Fig. 7. Transformer return-loss test setup.

Another consideration is the location of the 600-Ohm binding post, the 75-Ohm binding post, and the F connector. We placed the 600-Ohm binding post and the F connector on opposite ends of the long axis of the Beverage Box with the ground binding post placed on the side. In this way, the box could be "hung" from a Beverage. The F connector and 75-Ohm feedline hang vertically from the bottom of the box with no right angle bends in the cable and a natural drip path for the water off the box.

The Box

We chose an aluminum Hammond 1590 B box (109 × 58 × 25 mm), equivalent to Bud box number CU 124, because it was reasonably priced—in the $6.00 area—and had an inner lip which protects the circuitry from the weather. All seams in the box and connectors were coated with clear nail polish to form an inexpensive and watertight seal. Photo C shows a completed box.

Grounding

This is a subject all its own. But it is probably worth a few words here. The Beverage antenna will be erected only 8-15 feet off the ground. Therefore, it is unlikely to receive a direct hit from lightning.

F(MHz)	Return Loss (dB)	Vswr
1	20	1.22
2	30	1.06
2.7*	45	1.01
3	35	1.04
4	30	1.06
5	28	1.08
6	25	1.12
7	22	1.17
8	20	1.22
9	19	1.25
10	18	1.28
11	17	1.34
12	16	1.38
13	16	1.38
14	16	1.38
15-30	> 10	< 1.9

*Resonance in transformer produced (out of ham band) measurement anomaly.

Table 2. Transformer return-loss measurements.

To a certain extent, the feedlines to the Beverage Boxes act as counterpoises, since the most convenient route from the shack to the Beverage Boxes furthest from the shack was almost always along the ground beneath the Beverages. All feedline braids were grounded at each end. However, this counterpoise effect caused by the feedlines is not a designed-in part of the Beverage system and cannot be depended upon to either improve or degrade system performance. It just must be accepted as one result of this design.

In the installation of this antenna, several four-foot cable-TV ground rods were

used. In addition, several six- and eight-foot ground rods were used. Six-foot-by-3/8-inch or eight-foot-by-5/8-inch ground rods seem to be the grounding system of choice. But the best strategy seems to be this: Erect something, and if you are unsatisfied with performance, go out and add more ground rods a few feet away or add radials to the existing ground rod.

Incidentally, since no #6 copper ground wire was available, we simply used two strands of #12 (approximately equivalent to one #9 wire) to ground the termination boxes.

Place the ground rod a few feet away from the tree and you will have a better chance of avoiding thick roots when you drive the rod(s) into the ground.

Note that a six-direction Beverage system uses seven ground rods; the last one is for ground back at the shack. But you have already installed a good ground for your station, haven't you?

Wire and Height

Beverages will work best, it seems, at heights from 6 to 15 feet. Above that, they begin to look like conventional longwires. We caution you to put the wire up at least 10 feet, however, because one Massachusetts ham is now the defendant in a lawsuit resulting from a trespasser on horseback who was toppled from her horse when she hit the Beverage wire.

At K1VR, due to constraints imposed by lot size, the Beverages were only between 220 and 325 feet long. Widely-circulated folklore suggests that two wavelengths, or 450 feet at 80 meters, is optimum. There is some experience, at W4BVV and W1ZA, to suggest that 1000-1200 feet is too long at 80 meters.

Almost any wire will do, but we recommend stranded and insulated, approximately #16 or #18 AWG. Finally, if you want the wire to be seen, because you cross an open field perhaps, make it white or yellow. On the other hand, if you live in a more suburban area and wish to hide it a bit, choose green, brown, or black insulation.

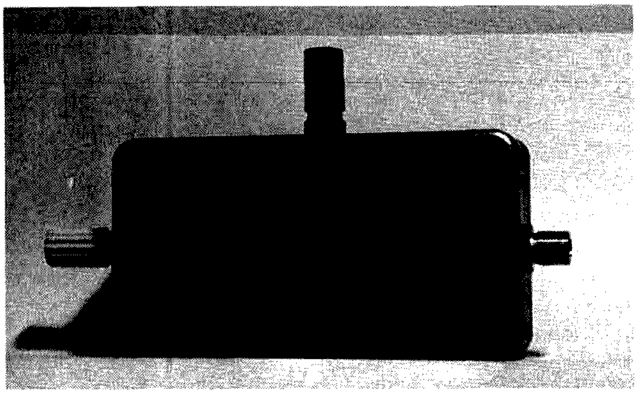

Photo C. Assembled and sealed Beverage Box. The system of three reversible Beverages at K1VR required six of these boxes.

The best mounting method yet discovered is to use standard electric fence wire standoff insulators made of plastic. They can be hammered into a tree in seconds.

Remember, when installing your wire, to keep it as far away as possible from towers and other metallic structures which may have the undesired effect of capacitive coupling. In the case where a 300-foot wire is supported in the middle by your tower, it is more likely to behave as if it were a 150-foot wire.

We chose stranded wire because, over such long runs, supported by trees, a solid wire would be flexed frequently, leading to stretching and breakage.

Conclusions

We set out to make a unidirectional receiving antenna for the low bands which would be very good for DX and reject signals from the side and back. For a modest amount of work, on a lot of modest size, we attained that goal.

Once we had the antennas up and working, we did notice something about their operation that deserved a bit of attention. Occasionally a signal seemed to peak on the wrong antenna. There are two reasons that this can occur. For one, a particular Beverage may not so much favor one direction as it nulls the interference coming from another. This gives the *appearance* of peaking a signal on the wrong antenna. In trying conditions, this means that some judicious switching is worthwhile. For another, Beverages are essentially low-angle antennas. As a result, a close (0-300 miles) station may actually be louder on the high-angle side lobe of a completely different direction Beverage than on the Beverage favoring that direction. At K1VR, this means that K2s often peak north or northeast. Locals, it seems, can peak almost anywhere.

Having established that we had a working antenna system and knowing full well that nothing good ever lasts, we decided to make records of baseline resistance measurements at the control head. There is variation due to feedline lengths, and maybe even grounding, but by measuring between the center conductor and ground at the output of the control head (removing the jumper that goes to the receiver), lines measured between 6 and 40 Ohms.

It is really neat to peak up the weak ones and reject the strong ones by changing directions so easily. If you've long bemoaned the noise and crud on 40, 80, and 160, try a Beverage and double your fun by feeding both ends!

Acknowledgments

Thanks to W1CF who erected the prototype version on Martha's Vineyard. And thanks to W1FC who took the first cut at designing the transformer. Both men work at M/A-COM, where we used some lab instruments for testing. Thanks also to N1BC for some helpful hints. K1VR thanks his company, Channel One, for offering a good deal on some RG-59 left over from satellite cable-TV installations.

We would be happy to respond to any inquiries accompanied by an SASE. ■

Join the Packet-Radio Revolution — Part II

Warm up your soldering irons.
This part offers the nuts and bolts of building your own TNC.

Lyle Johnson WA7GXD
c/o Tucson Amateur Packet Radio
PO Box 22888
Tucson AZ 85734

"You mean I can send messages error-free, experiment with various protocols, use amateur satellites without an amateur satellite station...? Wow! But you indicated I'd probably need this TNC to do it. How can I get one? Or better yet, how can I make one?"

Last month, a general overview of packet radio was presented. This time, a detailed description of the Tucson Amateur Packet Radio (TAPR) Terminal Node Controller (TNC) will be presented. I will do this in detail to allow the experienced home-brew artist to construct one, and I will make general comments regarding packet hardware. A look at current and projected packet activities will be included, along with references to sources of further information.

As explained in Part 1, most packeteers utilize a TNC to connect their radio and terminal or computer together. The TNC contains a microprocessor, memory, I/O for the terminal (from now on, the word terminal will be used to include a personal computer), I/O for the radio (including the modem, or TU), a power supply, and miscellaneous circuitry.

There are at present two TNCs in common use. One is supplied as a bare board from the Vancouver Amateur Digital Communications Group (VADCG) and was the first system generally available. It has 4K bytes of RAM space and 4K bytes of EPROM space. The 8085 microprocessor is utilized, along with the 8273 HDLC controller. An external power supply and modem are required for operation. (Contact VADCG, whose address appears at the end of this article, for more information.)

The second unit is a TNC designed by TAPR (pronounced "tapper"), and it includes 24K bytes of EPROM, 6K bytes of RAM, a 6809 microprocessor, and a Western Digital 1933 HDLC controller. It supports both serial and parallel terminal I/O and includes an on-board modem (with radio interface circuitry) as well as an on-board regulated power supply. The primary emphasis of this article is on building a TAPR TNC.

Short History of TAPR

The TAPR TNC came into being after a group of six hams got together in late November, 1981, following a presentation on packet radio by KD2S at the local IEEE Computer Society. After reviewing the October, 1981, *QST* article on packet radio, the group decided to get further involved. Wanting to do extensive experimentation with various protocols and desiring that the TNC be self-contained (with on-board modem, radio interface, and power supply), an informal club was formed and the name Tucson Amateur Packet Radio adopted.

An initial TNC design using a 6502 microprocessor was completed in December of 1981, and by late winter, a dozen PC boards were fabricated. These were called alpha boards, and the twelve people who had ordered them hurriedly assembled them. The software and protocol groups meanwhile got very busy, but work (the bane of an amateur's existence) got in the way and things developed rather slowly. The original boards had 12K bytes of EPROM, 4K bytes of RAM—and some very troublesome IC sockets.

By May, 1982, a FORTH compiler was resident on the TNC and some fairly crude software to exercise the hardware and ship packets was written. This system was first shown publicly at the ARRL Southwestern Division Convention, June 4–6. By this time, TAPR was a nonprofit R & D corporation with over 100 members. Shortly after the convention, stations WA7GXD and KD2S established packet communications over a 35-mile path in Tucson using the alpha TNC.

Investigation into the radio response characteristics of the 2-meter gear available to TAPR that summer showed that the audio response on a system basis (that is, looking at a signal from a receiver's speaker that was transmitted by another radio with a pure signal at its microphone input) was terrible. If the modem was to work at the tar-

get rate of 1200 baud, some filtering was going to be needed.

At this time, KV7B and KV7D stepped forward and volunteered to design such a filter. After careful study and computer simulation (meaning building and testing it on paper as opposed to actually doing it), a design came forth which was quickly breadboarded. On the second pass, it worked! Several radios were tested with the new filter, and most worked perfectly.

About the same time, the software people requested more memory space and an improved microprocessor. The 6809 was selected, and memory space increased to 24K bytes of EPROM and 6K bytes of RAM. And, again at the same time, an experiment believed to be unique in the annals of amateur radio history was launched...

Beta Test

It was a fundamental belief amongst the original TAPRites that unless packet were made available to the general amateur community as a tested and proven mode of communications, it would become at best a curiosity—like SSTV—rather than a dominant mode whose advantages could be readily exploited—like VHF FM. Thus, it was determined to do an extensive, nationwide test of the TNC design, both establishing it technically and creating a widespread organization with packet experience and expertise. We felt that in this way thousands of amateurs would get exposed to the new mode, see demonstrations, etc., and the TNC could be tested in a variety of climates and by people with all sorts of backgrounds, many nontechnical.

TAPR announced its intentions via its newsletter, *Packet Status Register*, and the *AMRAD Newsletter* (published by Amateur Radio Research and Development). By the cutoff date, over 160 amateurs agreed to participate in the test. It was made clear that a true test was to be done evaluating protocols, hardware, etc., that problems could be expected, and that solutions would have to come from the field, not just the Tucson "core."

In October of 1982, AMSAT sponsored a conference to decide protocol issues so the forthcoming Phase IIIB satellite could be used for intergroup-linking experiments. It was apparent that a standardized protocol was needed, or else different groups would not be able to exchange information. A sort of Tower of Babel would result, with each group speaking its own language. The result of this conference was the adoption of a protocol called AX.25, sponsored by AMRAD, with a few changes.

At TAPR, a software effort was organized to get this new protocol on the beta boards, and the race was on between the PASCAL coders with AX.25 and the FORTH coders with the TAPR/DA (dynamic addressing) protocol. The AX.25 team won the first round, and the resultant TAPR/AMSAT AX.25 protocol was burned into the TNC's memory.

After a false start in which 119 TNCs had to be scrapped due to a manufacturing defect in the PC board (see "Black Thursday" in the December, 1982, issue of TAPR's *Packet Status Register*), the beta TNCs were distributed. In a matter of a few short weeks, beta sites were on the air with packet beginning a rigorous test of hardware, software, and protocol. As this is being written, the first results of the beta test are flowing in, and by the time you read this, it is expected that the bugs will largely be exterminated in the software and hardware design modifications for enhanced operation will have been implemented.

The TNC

The information presented here for constructing a TNC is based on the latest hardware modifications. Be sure to contact TAPR for any updates before you begin building your unit just to be safe (please include an SASE), but you may be assured that the design presented here has in fact been put on the air by over 160 other hams and that it works very well.

CURRENT PACKET ACTIVITIES

Packet radio development is currently expanding in many directions:

On HF, transcontinental contacts have been made as well as short-distance ones, on 10 meters. AMRAD is sponsoring the design of a Packet Adaptive Modem (PAM) especially for HF use. It will work from 75 to 1200 baud using FSK techniques. The idea is that stations will establish contact at 75 baud and then step up the rate until the bit-error rate (BER) becomes too high (meaning too many retries). The units then will step down in rate and continue until either (a) the error rate degrades, meaning another step downward, or (b) the error rate becomes too good, meaning another step upward.

Another set of experiments has been conducted by W9JD using a scheme of forward error-correction (FEC). This means that redundant bits are sent for each character, slowing down the data rate for a given baud rate but allowing the receiving station to miss some bits and still get error-free copy! This sort of system no doubt will be further developed in the future.

On VHF, W3IWI and others have exchanged packets using OSCAR 8 Mode J! This is a precursor for the AMICON network to be established since the successful launch of Phase IIIB. TAPR is starting to design high-speed linking hardware for the Terracon application.

One of the most original experiments now being implemented is a device called PACSAT. This is an AMSAT-sponsored satellite that will fly in low Earth orbit (LEO) much as the present OSCAR series. However, this bird will have up to 4 megabytes of memory and will allow amateurs to send messages to other amateurs anywhere else on Earth. PACSAT will store the message until the receiving amateur logs in, at which time it will send the message to him. This store-and-forward system will allow non-real-time communications on a global scale. PACSAT is slated to fly in the 1985/6 time frame.

Back on the ground, several sites have put up computer bulletin boards on packet. The list includes San Francisco, St. Louis, Tucson, Washington DC, and many other cities.

A major breakthrough in packet communications occurred during October, 1982, when AMSAT sponsored a protocol meeting in conjunction with their annual meeting in Washington DC. Locked in a room until an agreement was reached, representatives from most active US packet groups met and adopted a "level two" protocol. This means that nearly every packet group will be running a common protocol, enabling us to "talk" to each other now that Phase IIIB is up! While seemingly perfectly obvious, such an accord will help prevent a Tower of Babel, allowing experimentation with access and modulation techniques for this satellite. Of course, each group can run whatever protocol they like locally, but most are now running the AX.25 protocol adopted at the Washington meeting.

As you can see, there is no lack of things being done with packet now, nor will there be in the foreseeable future. In fact, it is my opinion that the next year or so will see the beginning of traffic handling and emergency-communications-oriented amateurs reaping the benefits of packet-radio techniques.

The TNC design is broken into the areas of microcomputer terminal I/O, radio I/O and modem, and power supply. These will be discussed in some detail, and it is recommended that the builder thoroughly read this section before construction commences. The TAPR TNC incorporates some very new technology, some of it believed to be unique in the Amateur Radio Service.

NOVRAM (a trademark of Xicor) is a form of memory (nonvolatile) that doesn't forget when power is removed yet is easily updated by the operator. It is used to store such information as station callsign, terminal I/O characteristics (baud rate, parity, and stop bit options, etc.), radio channel information, and so forth.

A CMOS switched capacitor filter is used to smooth the radio system audio response to allow for a 1200-baud transfer rate. This filter is crystal-controlled, and its parameters are set by a network of 1% resistors so that it is economical (about $6 total) as well as reproducible (there are no adjustments nor critical capacitors).

"Byte-wide" memory is used, so the user can optionally mix the ratio of RAM and EPROM, and the address map for the microcomputer is burned into a TTL PROM, so it can be changed by those who so desire.

Other unique features include a 14-second "watchdog" timer to prevent a malfunctioning unit from tying up a channel, on-board self-calibration routines for setting the modem frequencies, and capability to select the HDLC baud rate under software control.

The Microcomputer

The TNC digital logic is implemented via a programmable microcomputer. This allows changes to be made in the logic (such as protocol definition) without modifying the board and greatly simplifies the device. To implement a TNC in discrete logic (such as TTL or CMOS ICs) would be an incredibly complex task and probably would render packet an unusable mode.

The design of the microcomputer portion of the TNC is very conventional. A crystal-controlled clock oscillator is implemented using two sections of a hex inverter, U1. The frequency chosen, 3.6864 MHz, enables the various baud-rate generators on the board to operate exactly at the standard baud rates in general use. A frequency divider follows the clock oscillator to provide a 1.8432-MHz signal for the 6551 UART (see User I/O, below) as well as a 115.6-kHz signal needed by the switched capacitor filter in the modem, described below.

A reset circuit is provided using two sections of a hex Schmitt trigger/inverter to provide a time delay after power-up. A switch is provided to allow the operator to manually reset the system as well.

The microprocessor is a 6809, selected for its architecture. It is efficiently able to run block-structured code such as that generated

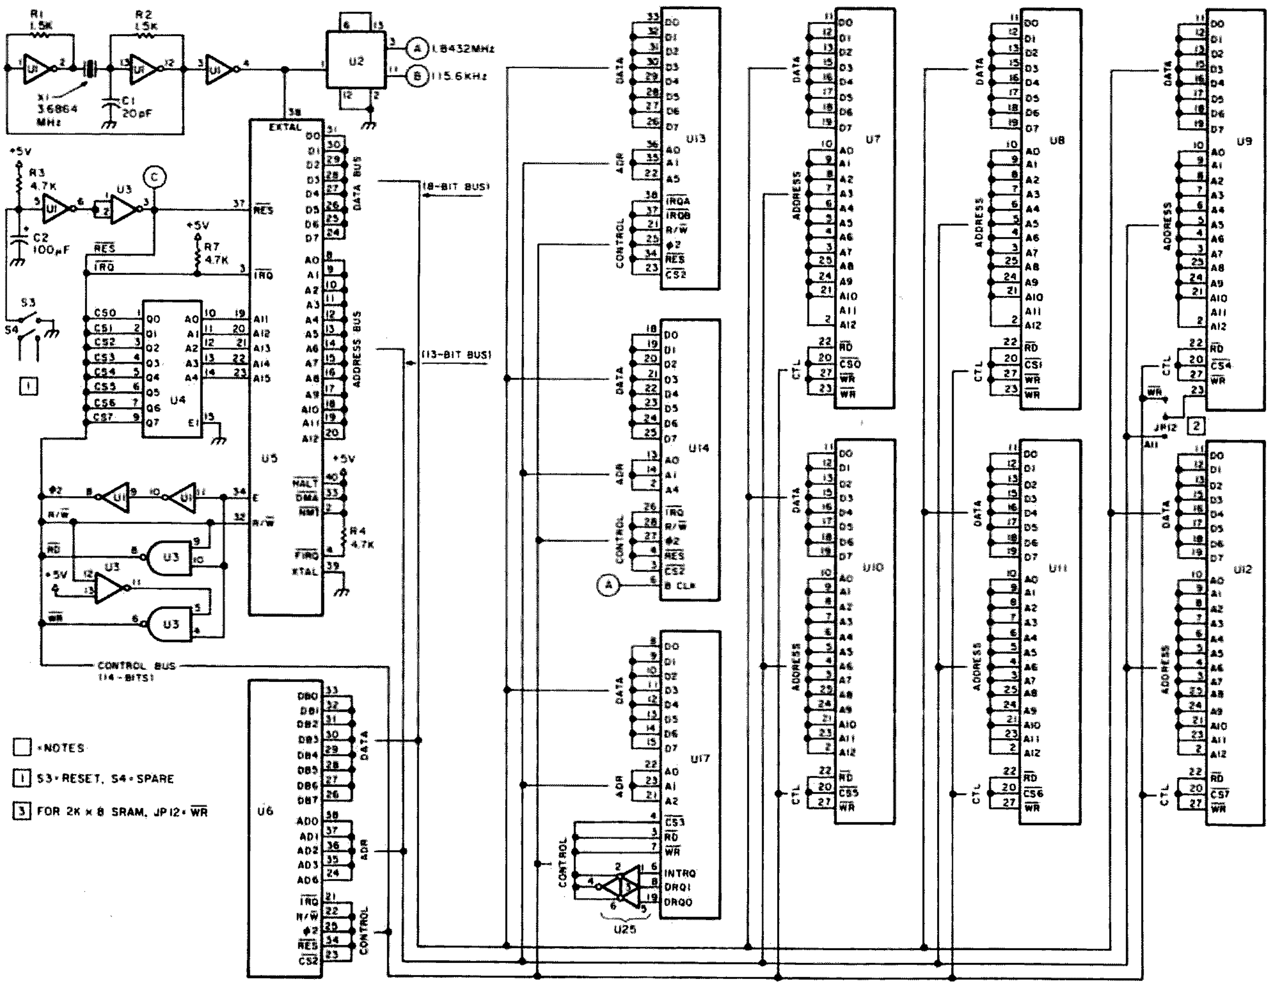

Fig. 1. System circuitry.

by PASCAL and FORTH compilers. Some additional circuitry is provided on the control bus to provide compatibility with the memory and HDLC controller. This is implemented using TTL for clock buffering and generating separate !RD and !WR signals. (Note that a leading ! means negative true logic in this discussion.)

The memory bank consists of six JEDEC-standard "Byte-wide" sockets. Each 28-pin site can accommodate RAM, ROM, EPROM, or EEPROM. The beta configuration calls for the low-order sockets, U7-U9, each to contain a 2K-byte static RAM chip (such as the AMD 9128, Toshiba 2016 or TI 4016) for a total of 6K bytes. The other three sockets contain 2764 EPROMs at 8K bytes each for a total of 24K bytes. This is more memory than many of the current crop of low-end "home" computers!

For maximum flexibility and to allow using higher-density memories (such as 8K-byte static RAMs, and 16K- or 32K-byte EPROMs), the address map is burned into a 32 × 8 bipolar PROM. This address decoder allows for any memory mix with a resolution of 2K bytes. Thus, a full 64K-byte address space can be accommodated with no changes other than burning a new address decoder PROM (at a cost of about $1.00)—and buying more memory, of course!

In order to allow the operator to store his station callsign only once (as opposed to storing it every time he turns the TNC on), as well as to allow flexibility in saving various serial port parameters (baud rate, stop bits, parity) and radio timing characteristics (key-up delay, hang time, etc.), a form of nonvolatile memory (NOVRAM) is incorporated into the TNC. 256 bits of this memory are provided. The interface is through a parallel I/O port (U6), simplifying the hardware design as well as protecting the NOVRAM from any glitches that might alter its contents in an unexpected manner.

This memory requires no batteries or other power to retain data for at least 10 years. It can be rewritten 10,000 times, or once a day for nearly 30 years! (Usually, it will be written to once or twice during initial setup, then only when the operator desires a "permanent" update, maybe once a month.)

The HDLC chip used is a Western Digital 1933B-00, selected for the fact that it contains a digital phase-locked loop (DPLL), used to recover clock information from the incoming NRZI data stream, and because it is the least expensive chip available which has this feature. Unfortunately, it wasn't designed just to hang on a 6809 bus, so a little TTL glue is needed to attach it.

Apart from the separate !RD and !WR lines, also needed for the memory system, the three interrupt outputs from the device are inverted and buffered by open-collector inverter sections of U25. Note that the data bus on this chip is in-

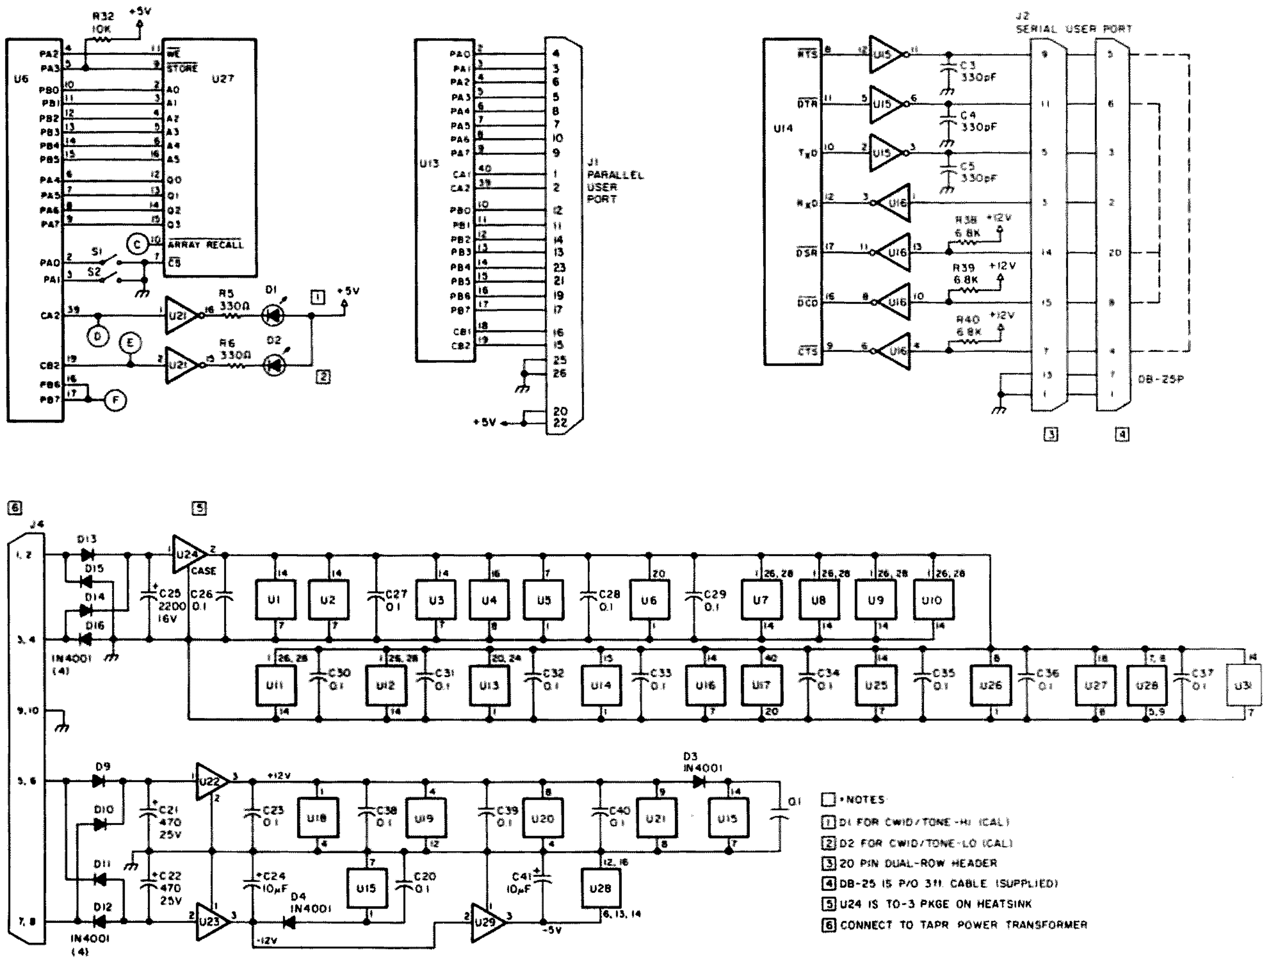

Fig. 2. I/O and power circuitry.

verted, so all data read from the chip must be complemented by the microprocessor before it is used, and likewise all data written to the HDLC controller must be complemented prior to writing.

The reset signal for the HDLC chip is provided by U6, which also provides the 32× baud-rate clock from one of its 16-bit programmable timers. The other 16-bit timer contained within the 6522 is used for maintaining several software clocks. These control such things as the CW ID interval, CW-character dot times, and so forth.

Terminal I/O

The operator interface consists of both a serial RS-232C port and a TTL-level dual 8-bit parallel port.

The most commonly used interface is the serial port. It supports the RS-232C voltage, current, impedance, and pinout specification, and the port looks like data communications equipment (DCE). This simply means that a standard terminal will attach to the port and work! If you choose to use a personal computer, it must look like data terminal equipment (DTE)—a terminal emulator. If your computer looks like DCE, a null-MODEM cable may be used.

The serial port is driven by a type 6551 UART (universal asynchronous receiver-transmitter), which is a 6809-family I/O device. It contains an internal, software-controlled baud-rate generator and can operate at all standard baud rates from 50 to 19,200 baud. Further, it supports 5- to 8-bit data widths, odd/even/mark/space/no parity options, and 1, 1½, or 2 stop bits.

The TTL levels from the 6551 are buffered and inverted by a 1488 driver (output) and a 1489 buffer (input). The output lines are loaded with 330-pF capacitors to ensure that the maximum slew rate of the RS-232C spec is not exceeded, while the 1488 driver is isolated from the power supply by a pair of diodes (D3 and D4) to protect the TNC from faults that may occur on the RS-232 interface. The connector on the PC board is designed to interface with a standard IDC connector and cable, the other end of which may contain a DB-25 crimp-on connector. The DB-25 will then have the correct pinout to attach to a terminal (DTE).

The parallel port uses no standard pinout, as no real standard exists for a bidirectional port of this type. It is included for completeness. An optional accessory for this port that turns the TNC into an EPROM programmer (for software bootstrapping) is available from TAPR.

Radio I/O and Modem

The TNC provides an audio signal for the microphone input of the radio transmitter, a "contact clo-

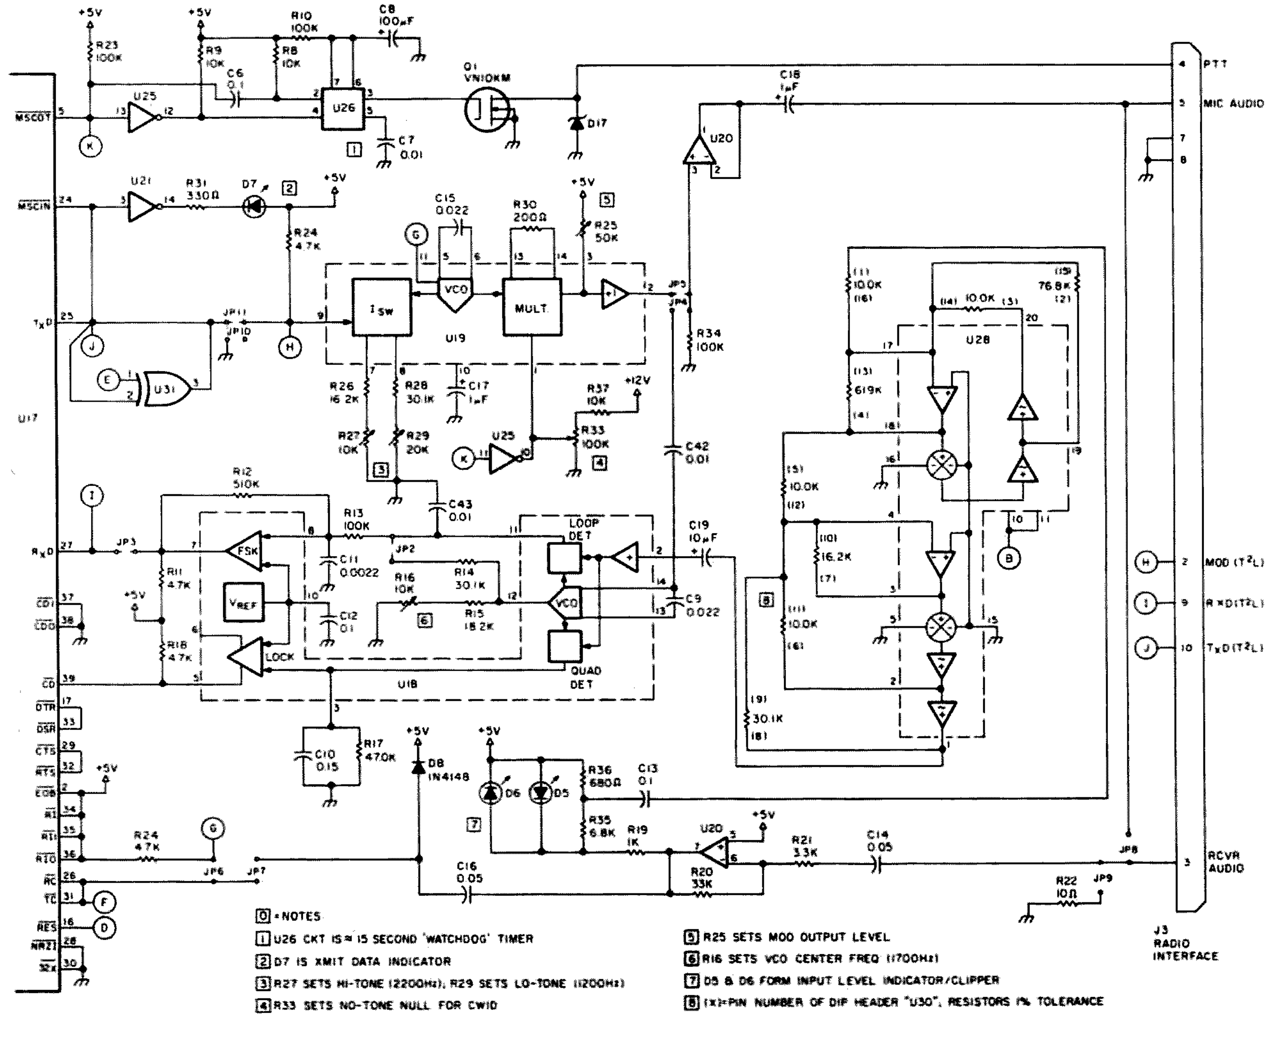

Fig. 3. Modem circuitry.

sure" to provide PTT actuation, and accepts audio signals from the speaker/headphone jack for reception.

The PTT actuation is accomplished via a VFET transistor, protected by a zener diode. When the TNC commands a transmit condition, the !MISCOT pin of the HDLC controller goes towards ground, activating the 555 timer. The output of the 555 biases the VFET on, providing an "on" resistance on the order of a few Ohms. This impedance is low enough to key every radio tested to date. When the transmission is completed, the !MISCOT line goes high, turning off the 555 and hence the VFET. Any voltage spike generated by the radio is suppressed by the zener, thus protecting the VFET and the TNC.

In the event that a glitch of some sort occurs (brownout?) during the absence of the station operator, the 555 timer acts to protect the channel independent of the microcomputer. The component values shown provide an approximately 14-second-duration maximum keydown time. This time may be increased and will need to be if the user plans to send long files at lower baud rates (such as might be required on HF frequencies).

The modulator is a phase-coherent FSK circuit using the popular XR2206 chip. This results in a low-distortion sine-wave output along with a simple, easily adjusted circuit. The output is buffered via an op-amp section before being passed to the radio I/O connector.

The output amplitude level is adjustable from a few millivolts to a few volts peak-to-peak and is typically set for 75 mV p-p. A null adjustment is provided and the tone keyed on and off for CW ID purposes. A square-wave output is also provided for connection to the 6522 PB6 input. This enables the software to configure a frequency counter for calibrating the modem to within a very few Hertz of the target frequencies.

The tone pair most commonly used is 1200 Hz and 2200 Hz for compatibility with amateurs using surplus Bell 202-style modems.

The receive side is somewhat more involved. The desired bandpass characteristic for using the Bell 202 tones is not met very well by unmodified amateur or commercial FM communications equipment. While a demodulator can be made to work by limiting and careful adjustment, it has been shown that the XR2211 PLL demodulator used in the TAPR TNC yields a performance improvement on the order of 3 dB when preceded by the switched capacitor filter shown in the schematic diagram.

The incoming signal is buffered by an op-amp section and then passed to a limiter/indicator using a pair of LEDs. The LEDs provide operator feedback for setting the volume of the receiver. The best adjustment is when the LEDs are just extinguished with an incoming signal.

A resistive divider then couples the signal to the MF10 switched capacitor filter. A second-order high-pass filter followed by a second-order low-pass filter then corrects the radio system bandpass characteristic. The filtered signal is then passed to the XR2211 PLL demodulator, where data carrier detection and data recovery are accomplished.

The MF10 filter has the advantage of not requiring any critical capacitors (nor any caps, apart from bypassing), relying instead on 1% resistors (cheap) and a crystal-controlled clock signal (already needed for the microprocessor). The result is an easily replicated filter characteristic with no adjustments!

The XR2211 circuit is very standard and reliable. The only changes made in the circuit recommended by the manufacturer are in the area of the data carrier detect filter capacitor. It was increased in size to help eliminate chatter and provide greater resistance to false indications due to noise.

Connections are provided to the demodulator to allow calibration by the same on-board frequency counter that is used to set up the XR2206 modulator. The result is an easily calibrated circuit that requires no special equipment.

If you desire, provision has been made for connecting an external modem for further experimentation and development.

FOR FURTHER INFORMATION

To find out more about packet radio, TNC boards, manuals, and parts kits, you may contact Tucson Amateur Packet Radio at PO Box 22888, Tucson AZ 85734.

There may be a TAPR beta site in your area. If so, talking on one of the local repeaters may lead you to someone with a packet station on the air. Numerous local groups are springing up, and many FM/repeater groups are beginning to incorporate packet operations into their systems.

Subscribing to *73* will provide you with other articles on packet radio, and other amateur magazines will also be carrying more and more information on this new mode.

Additionally, the following organizations have regular newsletters with packet information: TAPR, AMRAD, PO Drawer 6148, McLean VA 22106, and SLAPR, 1309 Gloucester Dr., Edwardsville IL 62025. Please include an SASE when writing to any of the above groups for information.

Packet promises to revolutionize amateur communications in the 80s much as did SSB in the 50s and FM in the 70s.

Power Supply

The TNC power supply uses full-wave rectifiers and series-pass regulators for stiff, low-impedance power sources. The design is very conventional and uses the 78/79XX series regulators for their excellent regulation, thermal overload protection, low cost, and wide availability. +12 V is supplied to the modem and RS-232 circuitry, while −12 V is used only for the RS-232 interface and −5 V is used only for the switched capacitor filter in the modem section. +5 V is handled by the more substantial LM309K, which may be mounted on or off board and supplies every subsystem on the TNC. Extensive bypassing is used (don't cheat and leave any out!), and no problems have been noted with crosstalk on the +5-volt bus.

Construction

With the foregoing as background, you are now ready to tackle the actual construction of the TNC. Please be warned, however, that the TAPR TNC is a complex piece of equipment, and construction by the faint-hearted or inexperienced is not advised.

While a wire-wrap job should yield a perfectly suitable unit, construction will be much easier if you elect to use a PC board. TAPR has blank boards available for a nominal price, and I suggest you write TAPR at the address given elsewhere in this article for details on price and availability. TAPR also has parts kits available, and you may want to take advantage of this service as well.

If you decide to obtain the parts yourself, consult the parts list for a detailed breakdown of the necessary items. It is OK to substitute many of the items (such as IC bypass capacitors) but be

Parts List

Part	Part Number	Description

certain to use temperature-stable components in the modem area and for the switched capacitor filter. Saving a few nickels here can lead to grief later on!

The software is available on a set of EPROMs. Source listings may be available, but they are bulky. Furthermore, unless you have a native-code PASCAL compiler for the 6809, the source code probably won't do you much good.

The TNC manual, available from TAPR, contains many details on operation, command structure, etc., that are simply too lengthy to print here, so obtaining this item is an absolute must.

Once you have all the parts, sort them out and organize them so you won't be fishing around for a particular resistor at midnight . . . anything you do to relieve tensions and frustrations as the building phase progresses usually pays off in reduced troubleshooting time after power-up.

The first construction step is to inspect carefully the PC board for shorts or opens. Use a magnifying glass, especially around the address decoder, the data/address lines on the top of the board in the memory array, and at the RS-232 buffer area. It is always possible that a board could get out that has an undetected flaw, and these are the high-density areas that are most likely to be troublesome.

The next step is to mount the IC sockets. Just tack-solder them in at the four corners, one at a time. (Use ONLY a low-wattage, temperature-controlled soldering iron with 60/40 or 63/37 rosin-cored solder.) When the socket is properly seated on the board, solder all remaining pins before going on to the next socket. You are less likely to miss a pin if you do it in this manner. Take your time, as it is much easier to be extra careful now than track down the cold or unsoldered pin later.

Next come the resistors. Be sure to double-check all values before soldering any of them in place. Follow these with the capacitors, paying special attention to polarity on the electrolytics.

Then solder in place the diodes, rectifiers, and voltage regulators. Don't mix up the 7812 and 7912 regulators—they can look the same at 2:00 am!

Finally, the crystal and connectors get installed. Be especially careful that you don't cause any solder bridges across the connector pins, as this can be disastrous!

Inspect the board for cold or otherwise poorly made connections. Be sure no lead clippings have lodged under the IC sockets and that no bridges occur between connections or foils.

If the board passes the visual inspection, set it aside. Wire up your power-supply transformer and radio interface cable, using connectors to match your radio. (You probably will find the appropriate connection information in the Radio Interface Appendix in the TNC manual; otherwise you will have to figure it out.) Incidentally, if your radio isn't mentioned in the interface section, please send a note to TAPR with the pertinent information (after you get it on the air and verify it, please!) for inclusion in future manual releases.

Now wire up your terminal/computer interface. If you are using an RS-232 terminal, you will find that an insulation displacement connector (IDC) at the TNC and terminal ends will work just fine, matching pin 1 of the TNC to pin 1 of the terminal connector.

Firing It Up

The first step in testing the unit is to power it up with no ICs in their sockets (you didn't use sockets . . . ?). Connect the transformer to the TNC and apply power. Using a voltmeter, verify that +12, +5, Gnd, −5, and −12 volts are all where they belong and within tolerance. *Be sure they are right* before proceeding with the next step.

Remove power from the TNC. Now ground yourself, the TNC, and the ICs. *Carefully* install the ICs in the sockets. If you mess up, use proper tools to remove the chip, and try again. Don't use a tool for removing the HDLC controller that doesn't allow for the hump in the middle of this chip or you will wind up with a pair of half-HDLC chips, neither of which will work . . .

A final inspection is in order now. It is advisable to have someone else inspect your work. Often someone not close to the project can spot something that you may consistently have overlooked. If all appears OK, you are ready for the smoke test!

Place DIP switch 1 in the closed position. Set your terminal at 300 baud, no parity, 8 data bits (same as 7 bits and space parity). Connect the terminal to the TNC and hit the return key (some terminals "stick" and the return key loosens them up). Apply power to the TNC. You should see the signon message appear. If you don't, or if you smell something like a burning TNC, remove power in a hurry!

Assuming all is working properly, you may now go through the calibration procedures as outlined in the TNC manual. If all is not well, consult the troubleshooting hints section of the manual for help.

You are now ready to join the ever-increasing ranks of amateur operators pioneering this new mode. Good luck! ■

Become a Low-Band Pioneer

Where does an audio transistor become a good rf amp? On 1700 meters, of course.

Seventeen hundred meters! This is the band of frequencies that gives you a chance to experience the world of long wavelengths. It can't fail to touch the imagination of the experimenter. Little attention has been paid to this FCC Part 15 band between 160 and 190 kHz even though it has existed for many years. Granted, there are strong limitations on antenna size and transmitter power as well as the fact that this isn't a true ham band. But it represents an opportunity for a first-hand view of the realm of low-frequency communications. With true ham resourcefulness and imagination some surprising things happen here.

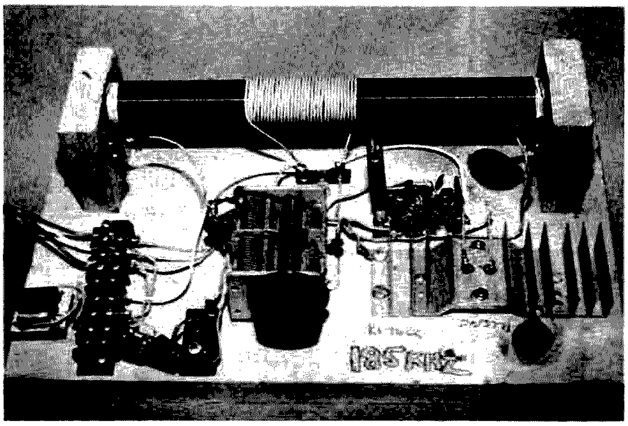

Photo A. The completed transmitter.

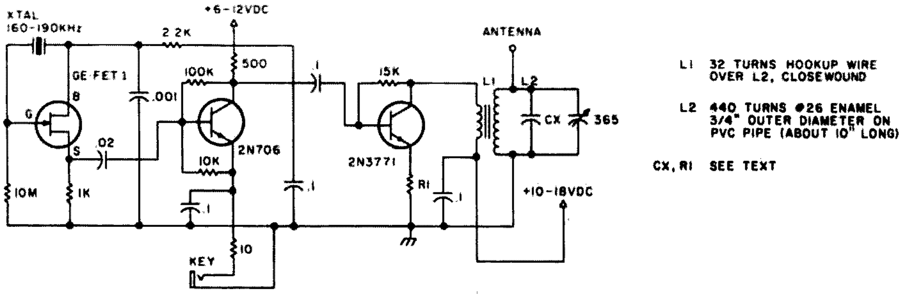

Fig. 1. 160-190-kHz CW transmitter.

The Rules

For those unfamiliar with Part 15, it deals with unlicensed radio transmitters that are permitted to operate under certain conditions. You may recall that toy CB walkie-talkies are legal . . . somehow. That somehow is Part 15. These regulations include a host of other services, such as industrial, scientific, and medical applications of radio. 1700 meters is specifically spelled out as an experimental band here and is free from some of the more restrictive rules concerning Part 15 in general. Anyone is permitted to operate an unlicensed 1-Watt transmitter using any mode for any purpose as long as the antenna is less than fifty feet in length. (Alternately, the power limitation can be calculated as not exceeding 15 microvolts per meter measured at 300 meters.)

So What Can I Expect?

Believe it or not, a CW or sideband signal into a good antenna can be heard for a hundred miles or more, even with these restrictions. While there are reports of ranges in excess of five hundred miles, the average station should be easily heard twenty to forty miles away. Today there is a small but growing number of amateurs—true radio pioneers—actually using this band for communications. Unfortunately, little information about it has been available to the average ham.

This article will be limited to the transmitting aspect of 1700 meters except to say that any number of commercial receivers available today will work well on this band when used with a good

antenna. An antenna that performs well for transmitting will work well for receiving. However, don't be deceived into thinking that just any long wire will work at these frequencies. It is likely you'll spend more time tuning up a 1700-meter antenna than anything you've ever assembled at higher frequencies. There will be more on antennas later.

The Transmitter

Building a transmitter at these low frequencies will come as quite a shock, especially if you've spent much time building UHF or microwave circuits. The tuning coils are monstrously large, lead lengths can be measured in feet, and audio transistors work great as rf power amplifiers.

This transmitter, as shown in Photo A, was a real breadboard design; it was built on an 8- × 14-inch piece of pine. This was done because of the inductive effects on the tank coil that would be caused by a metal enclosure. While this type of construction is not necessary, I recommend it for your first transmitter since it makes tuning up much easier.

The CW transmitter shown in Fig. 1 uses a GE FET-1 as a crystal oscillator feeding a 2N706 power amplifier. A 2N3771 is used as a final amplifier, although any NPN power transistor like the HEP247 or the SK3036 should work fine. Notice the lack of any tuned circuits until the final amplifier. When dealing with large coils, I've tried to keep their number to a minimum. The final tank coil, L2, is 440 turns of #26 enamel wire wound on a ¾-inch-outer-diameter piece of PVC plastic water pipe. The coupling link, L1, is 32 turns of single-conductor insulated hookup wire wound about the center of L2. An AM broadcast radio variable capacitor of 365 pF is paralleled with a 350-pF capacitor, Cx. This may have to be varied with individual transmitters, but this value is a good starting place for tuning 160-190 kHz. R1 in the emitter lead of the final amplifier is varied to produce the 1-Watt input required by Part 15. With 18 volts on the collector, I've found 15 Ohms is about right, but here again individual adjustments may be necessary.

There are several places to key the transmitter. The easiest is to simply key the emitter of the 2N706. If the transmitter is located a long distance from the operating site, a keying circuit like the one shown in Fig. 2 will control the transmitter by keying in 10 V dc. The current requirement is practically nil, so a long run of wire is possible.

Photo A shows the final transistor with a large heat sink. At one Watt, the final stays cold without the heat sink, but I've used this transmitter for experiments under Part 15 at higher inputs; that is why it is shown. A small IC ID generator can be seen attached to the terminal strip for use as a beacon.

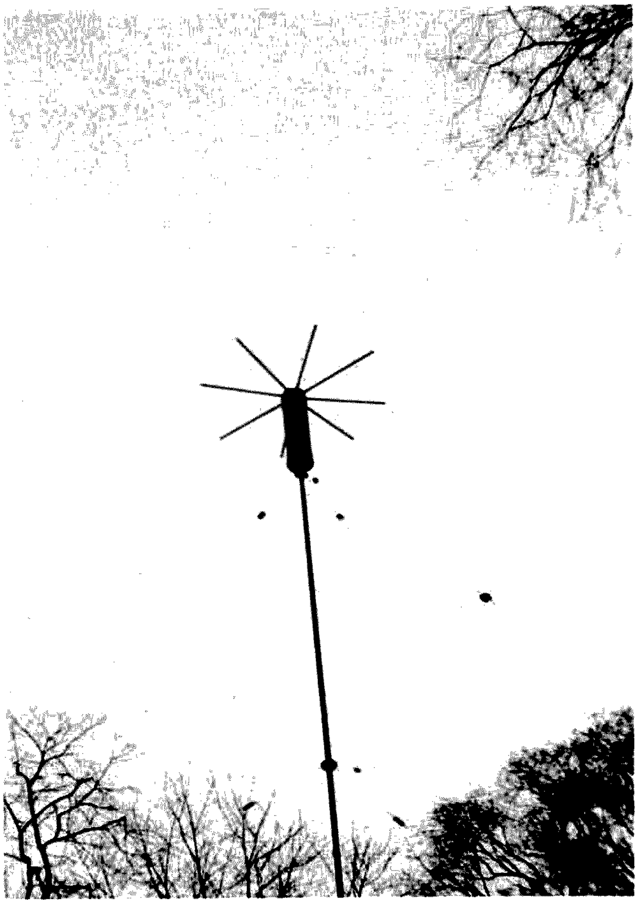

Photo B. The top-hat vertical for 160-190 kHz.

A simple LM555 timer (shown in Fig. 3) will key either the 2N706 driver directly or the circuit in Fig. 2, in a recognizable on/off pattern. This will allow you to distinguish your signal from others on the band, while doing remote measurements for antenna adjustments and so on.

Tune-up is simple. First listen on a receiver to make sure the oscillator is oscillating. Then tune C1 to resonance. A good indication is a glowing neon bulb placed across L2. With the high turn ratio between L1 and L2, the transmitter becomes a miniature Tesla coil capable of several hundred rf volts. Be careful that the tank circuit is dipped for 160-190 kHz and not harmonic. Using the values given for L1 and C1/Cx, this should be unlikely.

An Antenna

Antennas for 160-190 kHz are an entirely different subject. Since you are limited to fifty feet in length, each antenna will be an individual unlike any other. It will be necessary to experiment to get the best combination of values to achieve maximum radiation. These values will depend on local conditions such as soil conductivity, proximity to metallic structures; the list is endless. Here are a few guidelines to follow. Stay strictly with vertical polarization since losses from horizontal antennas are severe given the limitations of fifty feet. Use a high-quality base insulator because you'll be dealing with high rf voltages even at 1 Watt. Also use the best grounding system you can construct. Lastly, listen with a receiver at a considerable distance from the antenna and adjust the combinations of loading coils, grounds, etc., to produce the best S-meter readings. Be prepared to do a lot of experimenting (and learning), but eventually your efforts will be rewarded as you're able to add more and more miles to your communications range.

Fig. 4 is an antenna I've used and one which others can be patterned after. L2 of the transmitter is grounded on one side and the other is fed by a heavy copper strap to the base of a large diameter copper pipe. At the top of this guyed mast is a capacity hat and a loading coil. The coil is made of #26 enamel wire close-wound on a 4-inch-diameter piece of PVC pipe. The number of turns is somewhere in the neighborhood of 1500, and as I said, there are some monstrously big coils at these frequencies.

The transmitter is located directly over an old 60-foot-deep well with a 4-inch iron casing. This and numerous radials make up the ground system. This transmitter and antenna radiate a signal that can be consistently heard over twenty-five miles, which isn't bad when you consider the limitations of using a very short antenna with wavelengths approaching a mile.

During the last WARC, 160-190 kHz was proposed as a ham band. Perhaps if interest grows it will find its way among our frequencies. Right now it is still a great place to explore. ■

Parts List

Crystal

160–190 kHz	$12.50	from Jan Crystals, 2400 Crystal Drive, PO Box 06017, Ft. Myers FL 33906. (Suggested frequency range of 180–190 kHz since this is where most serious operation is done.)

Transistors

1 GE FET-1	$2.00	SK3112 also suitable.
1 2N3771	$4.50	SK3036, HEP247, or other power NPN transistors are suitable.
1 2N706	$1.00	2N2369A, SK3122 are suitable.
optional		
1 40250	$4.00	SK3026 also suitable. Used for optional remote control of transmitter.

Resistors

1 10 Ohm	All resistors are ¼ Watt, 10%. Cost: approximately 20¢ each.
1 500 Ohm	
1 1k	
2 2.2k	(only one required if optional remote control is omitted)
1 10k	
1 15k	
1 100k	
1 10 megohm	

Capacitors

1 .001 Ceramic	Capacitors from grab-bag-type assortments available from Radio Shack.
1 .02 Ceramic	
4 .1 Ceramic	$2.00

Random combination of silver micas to total 350 pF.
Micas available from the same above sources, if purchased separately at 25¢ each.

1 350 pF variable	$1.00 from a local hamfest. Also, old BC AM radios.

Miscellaneous

1 2-watt resistor for emitter of power amplifier transmitter, to be experimentally calculated, to limit input to 1 Watt. (A safe bet is 25 Ohms for a 15-volt supply.) 25¢

1 2-foot section of PVC pipe for coil form. See text. A scrap item.

1 10- × 14-inch piece of ¾-inch pine breadboard, another scrap item.

MICROLOG

AIR-1

SPECIFICATIONS

INPUTS: Receiver audio, in & out phono jacks for easy speaker connections. Hand key input allows code practice that reads your sending and drives the transmitter keying outputs.

OUTPUTS TO TRANSCEIVER: Positive and negative switching for CW & FSK keying, solid state or tube type transmitters, AFSK tones at microphone compatible levels, T/R(PTT) transmitter control.

PRINTER OUTPUT: Uses standard VIC printer for "Hard-Copy" of both receive and transmit data regardless of on-the-air mode. Also has hi voltage transistor switch on board for driving current-loop type printers.

DISC & TAPE INTERFACE: Uses standard VIC DISC & DATASET for recording off the air and making long "brag tapes." Another handy feature is the ability to save and re-load your "here-is" memories easily. Since this function is also compatible with your VIC disc drive, it's especially nice for quick start-up.

VARIABLE MEMORY UTILIZATION: A unique Microlog feature allows you to select the size of your text buffer and 8 "HERE-IS" messages from the available computer RAM. It automatically takes into account any memory expansion cartridges you've added. The unexpanded VIC has about 3000 characters for you to allocate. You could for example choose eight 300 character messages and a 600 character text buffer. If you don't tell it otherwise, the system will default to eight 100 character "HERE-IS" memories and a 2200 character text buffer. The expanded VIC will have different default memory sizes, depending on the amount of added memory. The programmable "HERE-IS" memories can be loaded or inserted into the text buffer for transmission at any time.

TEXT BUFFER: Allows you to type ahead while receiving. Text entered into the buffer is visible above the split-screen line for correction before sending.

AUTO-START: Inhibits the display of non-RTTY data.

TUNING INDICATORS: On screen visual tuning aid and audio (pitch) reference tone for RTTY and CW. (Audio is heard thru your tv or monitor's sound channel, just like any other VIC generated audio.)

W R U (Who Are You?): Automatically responds with your call sign when a user programmable sequence up to 15 characters is received.

SEL-CALS: Two 15 character user programmable sequences. Receipt of selcal #1 enables the printer, disc or tape. Receipt of #2 disables these outputs for unattended message store (mailbox).

FULL SPEED OPERATION: Transmit and receive Morse — 5 to 199 WPM, Baudot — 60, 66, 75, 100, 132 WPM, ASCII — 100 & 300 baud.

MORSE SPEED TRACKING: Automatic and speed lock modes, keyboard selectable.

VIDEO DISPLAY: Color keyed display makes optimum use of the computer's color capability. Uses standard VIC format of 23 lines of 22 characters.

SPLIT-SCREEN: Displays text buffer input above and receive/real-time transmit text below the split line.

TOP LINE DISPLAY: Constant display of Time, Mode, Speed/Code in use, and status indicators.

TEST MESSAGES: Quick brown fox and RYRY's in Baudot, U*U* in ASCII, and VVV in Morse.

SPECIAL SYNC-LOCK MODE: Allows improved ASCII operation and "Paced Output" in Baudot RTTY.

T/R(PTT): Fully automatic control of your XMTR via the Push-to Talk line in both RTTY and Morse.

UN-SHIFT on SPACE: Automatically shifts back to "LETTERS" upon receipt or transmission of a Baudot space. Keyboard command on/off.

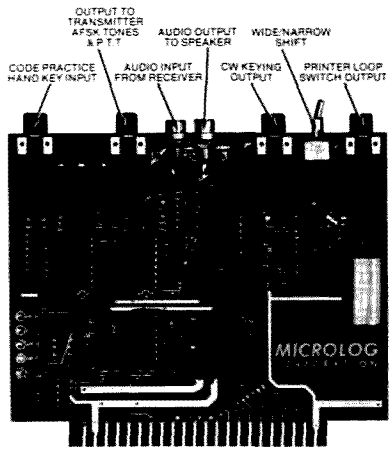
SYNC: Transmits "Blank Fill" in RTTY and BT in Morse when the text buffer is empty and unit is in transmit. Keyboard command on/off.

OUTPUT MODES: CHAR — outputs each character as typed. WORD — outputs full word when spacebar is typed. LINE — outputs full line when carriage return is typed. BUFFER — outputs full buffer, on command.

REAL-TIME CLOCK: Uses the VIC's internal clock for constant on screen display of time which can be inserted into text buffer on keyboard command.

WORD WRAP AROUND: Prevents splitting words at the end of a line. Works in receive as well as transmit.

MORSE TONE DETECTOR: Single tone, 800 Hz center frequency, with effective bandwidth of 300 Hz. Pitch reference regenerated audio tone for easy tuning.



RTTY DEMODULATOR: True dual tone computer enhanced demodulator circuit on standard 2125/2295 Hz tone pair compatible with HF RTTY and VHF FM operation. Switch selected wide and narrow shift.

CODE PRACTICE: Random five character code group generator sends at any speed you set via the keyboard. Hand key input for sending practice and manual morse transmission.

CW ID & NORMAL ID: Two independent 16 character memories for either 2 calls or one normal and one with auto-CW ID for RTTY.

MECHANICAL: Printed circuit board is G-10 epoxy, double sided with plated thru holes. Board is solder masked and silk-screened with parts locations for easy troubleshooting. Size is 5¾" wide by 4½" deep by ¾" high. Fits directly into VIC expansion port and is compatible with popular expander boards in use.

NO EXTERNAL POWER REQUIRED: Unit is completely powered by host computer, eliminating the need for outboard power supply. (Entire system; VIC, Microlog AIR-1, & video monitor can easily run from 12 VDC power for remote or emergency battery operation.)

CONNECTIONS: All inputs/outputs are convenient ¼" 3 circuit phone or RCA phono types. Mating plugs are all provided.

Note: VIC, VIC-20 and DATASET are trademarks of Commodore Electronics, Ltd.

INNOVATORS IN DIGITAL COMMUNICATION

The Phantom Antenna of Possum Hollow

The boys needed a good antenna fast—before winter set in. Thurman's mysterious story was the solution.

W. Brandon Randolph W8VFT
895 Clifton Road
Xenia OH 45385

The Saturday night meeting of the Possum Hollow Radio Club had to be the high point on the monthly social calendar. The only other activities that rivaled club meeting were Wednesday Night Prayer Meeting and kicking Little King Ale bottles along Route 68. Possum Hollow was one of those unique places where time appears to stand still.

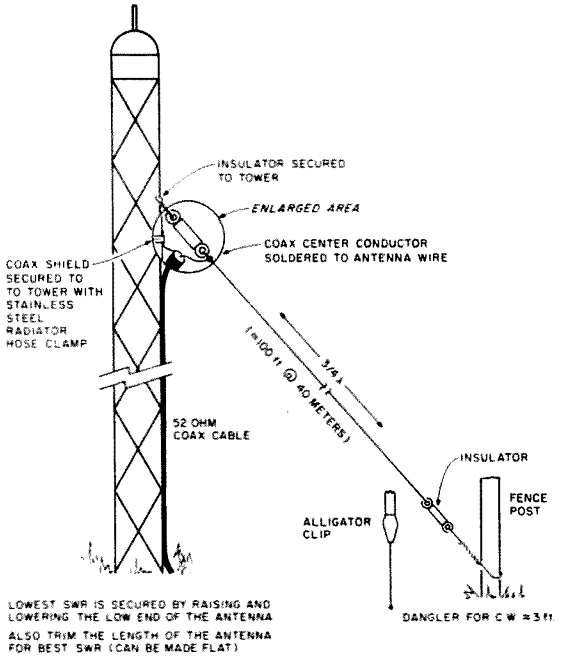

Fig. 1. The 3/4-wavelength Extended Sloper Antenna. The length of the dangler will be the difference in length of the measurements calculated for the phone band and those for the CW band.

The lack of something exciting to do, in this out-back community, might explain the club's popularity.

Because the club shared the old Possum Hollow schoolhouse with the local Grange, the furniture was arranged as if for a fraternal lodge meeting. The wisdom of the founding fathers had preserved the one-room school intact, up to and including the large, ornate potbelly stove in the corner.

Since this was an agricultural community, the summer meetings were dispensed with and the fall harvest signaled the resumption of the monthly get-togethers. By this time of year, a small fire in the stove was much appreciated by everyone.

Thurman, the club treasurer, had made sure that his desk was near the stove. Since he was the technical expert of the club, his desk was the favorite gathering place.

The last bang of the president's gavel signaled the end of the business meeting and the time to break into little groups, like women at an old-fashioned quilting party. The technically-minded quickly grabbed folding chairs and slid in close to Thurman's desk. This part of the meeting was the lifeblood of the club and the part of the meeting that attracted the majority.

This particular meeting was held on a nippy fall evening and the fire felt good. The snapping, crackling sounds added to the festivity and good fellowship. Before the last sound of the president's gavel had died away, the usual gang was crowded around Thurman's large wooden desk.

"Thurman, got any good ideas for a 40-meter DX antenna that I could string up before bad weather? Something not too expensive or elaborate."

Thurman looked up from the records he was working on and grinned.

"Not looking for much, are you, Ernest T.?"

"Well . . . guess that is a big order, but I figured if anyone could help me, it'd be you, Thurman."

Thurman closed the record book he had been working on, smiled, and placed his pencil behind his ear. Leaning back in his swivel chair, he turned slightly.

"Ernest T., you're in luck. I just finished a new antenna this summer and from the reports I've been getting from Europe, I'd say it's going to be a honey."

"What do you call it, Thurman?"

"Oh . . . I call it an Extended Sloper."

"What the heck is an Extended Sloper?"

Thurman's eyes twinkled as he tapped his pipe in the ashtray on his desk. He knew that he had Ernest T. on the hook. Thurman loved to spin a yarn, and this new twist on an old antenna would give him plenty of mileage. He lit his pipe and continued.

"Remember that quarter-wave sloper I had on my tower a while back?"

"Sure do," replied Ernest T.

"Well, I reasoned that if I lengthened it to 3/4 wave and aimed it toward Europe, it should have a little more gain and some added directivity." Thurman tilted his head back and blew a thick, undulating smoke ring—and waited.

"Well . . . did it work?"

"Sure did—and it loads up fine. Takes a little playing with for the exact length and height at the low end, but it's worth it and I'm getting excellent reports." With this statement several chairs slid in closer.

"How about a diagram, Thurman?" chimed in several voices in unison.

"OK, fellows, no problem. Its design is exactly the same as any other sloper with the exception of its length. Calculate the length for a quarter wave and then multiply by three."

"That's all there is to it?" asked Ernest T.

"That's all."

Otis had been leaning back in his chair with first one foot and then the other propped against the ornate trim on the potbelly stove. He now leaned forward and looked intently at Thurman. A look of disbelief was written across his face.

"You mean to tell us that you can load that odd length of wire?"

"I certainly can . . . and by adjusting the height at the low end and trimming the length, I can get the swr perfect. The best thing about the antenna is that I cut a 'dangler' piece of wire with an alligator clip attached, and I'm able to operate both phone and CW with perfect swr on both."

"What band you got it on, Thurman?" asked Forrest.

Thurman glanced around at all the inquiring faces and smiled. He withdrew his pipe from his mouth and slowly answered as if he was thinking of something.

"Well sir, it's on 40 meters. Look here, fellows—I'll draw you a diagram. It's very simple." He drew them a diagram and everyone scooted closer to watch. After he had finished putting in the figures, each observer made a rough sketch for himself.

"See, I told you it was easy. Just like a quarter wave, but extended. That's why I called it an Extended Sloper."

"Come and get it . . . Come and get it!" called Ramsey, the club refreshment coordinator. He was motioning for everyone to come to the table where the coffee pot and doughnuts were waiting. Tonight, fresh cider was on the table, and the thought of cider and doughnuts relegated the copies of Thurman's antenna diagram to shirt pockets.

Thurman chuckled to himself as he tidied up his desk and walked to the refreshment table. "Bet I'll be pruning some antennas next week," he thought to himself. ■

NEW EGBERT II RTTY--CW for THE APPLE COMPUTER SOFTWARE ONLY

NO TU REQUIRED

Many Standard and UNIQUE FEATURES
(ALL ON ONE DISK)
any MARK and SPACE frequency
500 Hz to 3000 Hz

CAN BE USED WITH TTY FOR THE DEAF
Requirements: Apple II 48K, 3.3
TRANSMIT OR RECEIVE

ALSO ACCEPTS TTL INPUT TO GAME I/O
C.W. VERSION AVAILABLE

PRICES: RTTY **$39.95**
Back-Ups each .... **$ 7.50**
C W **$39.95**
RTTY with CW **$59.95**
*Shipping .... **$ 2.50**

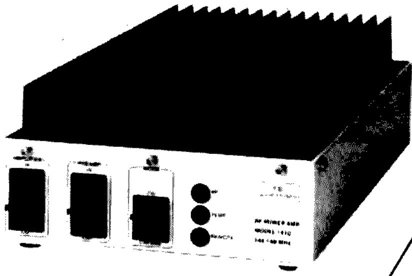
A DESIGN EVOLUTION



- Linear (all mode) RF power amp with automatic T/R switching (adjustable delay)
- Receive preamp option, featuring GaAs FETS (lowest noise figure, better IMD). Device NF typically .5 dB.
- Thermal shutdown protection incorporated
- Remote control available
- Rugged components and construction provide for superior product quality and performance
- Affordably priced offering the best performance per dollar
- Designed to ICAS ratings, meets FCC part 90 regulations
- 1 year transistors warranty
- Add $5 for shipping and handling (Cont. U.S.). Calif. residents add applicable sales tax.
- Specifications/price subject to change

MODEL 1	FREQUENCY 2	OUTPUT POWER	INPUT POWER	SUGG. PRICE LESS TAX
	(MHz)	(W)	(W)	$
1410 1410G	144	160	10	225 265

Your Enemy, Feedline Loss

Let your swr meter stop this demon before it creeps up on you.

Martin K. Salabes K3CSV
1400 MacIntosh Boulevard
Nokomis FL 33555

If the performance of your antenna system seems to be deteriorating, the problem, or at least part of the problem, may lie in the coax connecting the transmitter with the antenna. Coax is subject to deterioration, especially if moisture can enter through the connectors or if there is a rupture in the vinyl sheath. Fortunately, there is a simple and fairly accurate way of measuring coax loss, using only an ordinary swr bridge.

When the frequency of a signal fed to an antenna is much lower than the resonant frequency of the antenna, the swr *at the antenna* will be infinity, or approaching infinity. In other words, all of the energy fed to the antenna will be reflected back. However, if the swr is measured at the transmitter end of the coax, the swr will be somewhat lower than infinity because not all of the forward energy reaches the antenna due to the loss in the coax, and not all of the reflected energy returns to the swr bridge for the same reason.

Most swr bridges actually indicate rectified rf voltage, although they are calibrated in swr. These voltages are relative, of course, and can be read on a linear scale. (If your swr bridge does not have a linear scale of some kind, one can easily be improvised.) So, all that is necessary to determine coax loss in dB is to read the forward and reflected relative voltages on an swr-bridge linear scale (while using a signal frequency much lower than the resonant frequency of the antenna) and plug these voltages into the standard equation for dB in terms of voltage: $dB = 20 \log_{10} V_1/V_2$, where V_1 = forward voltage and V_2 = reflected voltage.

As a voltage ratio is required for this equation, only relative voltages are needed, not actual voltages. Of course, the loss obtained this way is "round-trip" loss and is twice the loss experienced in normal use. One caution: As the transmitter is working into a very high swr, use as little output as possible and for as short a time as possible.

For example, suppose we feed a small 40-meter signal into a 10/15/20-meter beam. Adjust the swr bridge to read full scale forward (10 on the linear scale). Switching now to reflected, it reads 8 on the linear scale. Round-trip loss is therefore: $dB = 20 \log_{10} 10/8 = 20 \log_{10} 1.25 = 20 \times .097 = 1.94$ dB = a coax loss of .97 dB one way. Whether this is high or not will depend, of course, on how long the coax is. Check with the manufacturer's specifications for that particular type of coax.

If you are fortunate enough to possess or have access to a bidirectional wattmeter, the measurement is even simpler. As before, feed a signal into the antenna that is much lower in frequency than the resonant frequency of the antenna and measure forward and reflected power. Now just plug these values into the equation for dB in terms of power: $dB = 10 \log_{10} P_1/P_2$, where P_1 = forward power and P_2 = reflected power. As before, the loss obtained will be round-trip loss; one-way loss will be half as much.

One symptom of coax loss is an improving swr of your antenna system. As the coax deteriorates, less forward energy reaches the antenna and less reflected energy returns to the swr bridge, giving a false indication of an improved swr. If this is happening but your rig's performance is not what it used to be, check the coax loss. If it is much higher than the manufacturer's spec says it should be, just replacing the coax might make a world of difference. ■

PVC Meets VHF

Flush high cost down the drain and build these cheap antennas. The gain is free.

Occasionally an antenna is wanted which is compact, cheap, and easy to make. Being inventive and a bit short of cash, I came upon this solution to fill the requirement for a couple of antennas I needed.

The following material was purchased at the local hardware store for the sum total of four bucks including tax; certainly, if purchased in a specialty store, you might save another buck:

- 5 feet of PVC water pipe, 1/2-inch i.d.
- 3 feet of copper tubing, 1/4-inch i.d., type L
- 2 PVC caps to fit PVC pipe

RG-58 coax, approximately six feet of it, was salvaged from the junk box. BNC or PL-259 type connectors, as required, also came from the junk box. These materials are enough to make a 2-meter and a 3/4-meter antenna.

Construction of the 3/4-meter antenna is as follows. Cut a length of approximately 20 to 24 inches of RG-58 coax. Strip the outer insulation for about eight inches. Remove most of the shield, leaving a section about 3/4 to 1 inch long. Do not remove the insulation from the center conductor. It will provide for support of the radiator.

Cut a piece of copper tubing about 7½ inches long; using either a tubing cutter or hacksaw, deburr ends. Using steel wool, clean one end of the tubing. Neatly tin the cleaned end.

Carefully slide the tubing over the coax and fan the piece of shield over the tubing. Measure where the tubing ends and wrap a few layers of tape around the coax to protect it from the sharp edge of the tubing. Slide the tubing back over the coax. Fan the shield back over the tubing as evenly as possible and carefully solder the shield to the copper tube. Use a large iron or a soldering gun, working quickly to prevent the center insulation from melting. If you find it difficult to solder the fanned shield, it can be tied down with a very thin strand of copper wire. That worked really well for me.

When the tubing has cooled, check with an ohmmeter for short circuits between the center conductor and the copper tubing. If all is OK, proceed to the next step.

Cut off 18 inches of the PVC pipe and slide the antenna into the pipe.

Mount a connector at the free end—either a BNC or PL-259; check again for short circuits.

Check swr with the antenna assembled; the PVC pipe will affect the swr somewhat. Prune as required. Trim the radiator only—don't try to shorten the copper tube.

When the swr is acceptable (less than 1.5 to 1), final-assemble the antenna inside the PVC tubing (a few turns of tape at the lower portion of the tubing will help hold it in place). Glue one of the caps on the top of the pipe and a grommet at the bottom end to keep the feedline centered.

The 2-meter antenna is made exactly the same way except for the dimensions. The copper tubing is cut to 18.5 inches. A 4-foot or longer piece of coax is stripped 19 inches. And the PVC pipe is cut to 41 inches.

Build and test the same way as the 3/4-meter antenna. To provide better support inside the tubing, wrap three bands of tape around the tubing to provide a tight fit inside the PVC pipe. I supported the center conductor inside one VHF antenna with a handy 1/2-inch-o.d. faucet washer; this kept the antenna nice and quiet, too.

These antennas are, obviously, 1/2-wave centerfed dipoles; they were very popular some years ago. They have fallen out of favor to the newer high-gain (3-dB), base-loaded, $40.00 antennas that are now flooding the market. These coaxial antennas perform somewhere between 1/4-wave and 3-dB-gain antennas in terms of gain; not bad for 2 bucks each!

The final tuning procedure should be done in a clear area with as little metal around as possible. Prune the antenna 1/8″ or less at a time, especially the 3/4-me-

ter version. However, if you over-trim, it's easy enough to solder a piece of wire back on the radiator to lengthen it. When completed, the antenna can be sealed at both ends with RTV compound for total weather protection.

Use the best quality coax possible and it will not present any problems either during soldering or at any other stage of the construction. It also will last longer if the antenna is mounted on a tower and is exposed to all kinds of weather.

The antenna can be mounted in a variety of ways using easily-available clamps and brackets. Since these antennas are very unobtrusive, they also can be mounted either inside the ham shack or out of sight in a kitchen corner.

For those who have more ready cash and room, a somewhat better antenna could be made using RG-8/U coax and correspondingly larger diameter (1/2"-i.d.) copper tubing and (1"-i.d.) PVC piping. The other dimensions should stay the same.

This same principle also works well for a marine band VHF antenna, either as the main antenna or an emergency antenna. It can be tied to almost any unobstructed non-metallic (sailors take note) part of a boat—or even hand-held if necessary. The dimensions for this antenna should be: 40 inches of PVC pipe, 18 inches of copper tubing, and 48 inches of coax.

Construction and tuning are the same as for the 3/4-meter and 2-meter antennas. Provide a loop of nylon line at the top so that it can be hoisted and suspended by it. When using the antenna, seal the coax connectors with a plastic bag and tape to keep water and dampness out. ■

ALL HF BANDS!

The SLINKY DIPOLE® Antenna

A broadband, low SWR dipole that really works in apartments, small yards, attics, anywhere a small antenna is a must. Indoors or out, you can work ANY HF BAND, including 10 MHz. No gimmicks or add-ons. Imagine 80M in as little as 24 ft.! Complete kit and instructions, plus 50 ft. of coax. Easy to set up and adjust. More information available - just call or write.

A 10-MHz Antenna for $10

If you're still not on 30 meters, the Hanging Helix may be your last chance.

Guy Slaughter K9AZG
753 W. Elizabeth Drive
Crown Point IN 46307

The old-fashioned delta loop, when fitted with a newfangled "Hanging Helix," makes a cheap but superb antenna for the recently opened 30-meter band.

You've never heard of a "Hanging Helix"? Me neither. It's just a name I coined for a gadget I made to perform multiple-duty assignments on a 10-MHz antenna, or one for any other band.

A full-wave loop, whether in quad or delta form, presents a feedpoint impedance of around 100 Ohms at normal heights above ground, depending somewhat on the nature of surrounding objects. And it is a balanced antenna whose radiation pattern and, hence, efficiency suffer when fed with an unbalanced feedline.

It is necessary when mating a full-wave loop with a 50-Ohm feedline, therefore, to contrive both an impedance-transforming system and some sort of a balanced-to-unbalanced conversion device.

The Hanging Helix performs both these functions, plus two mechanical chores as well. It is a quarter wavelength of 75-Ohm RG-59/U coaxial cable wound into a coil on a homemade form that also serves as the antenna's feedpoint insulator and as the anchor for the feedline. Thus, it converts the antenna's 100-Ohm-plus feedpoint impedance to the 50 Ohms of RG-8 mini-coax and acts as a choke-type balun preventing antenna currents from appearing on the shield of the feedline to alter the antenna's radiation pattern.

This multi-purpose gadget is easy to make from commonly available materials. In use, it converts a full wavelength of wire hanging from two trees—or two anythings—into an efficient and rewarding antenna.

When the new 10-MHz band was suddenly opened last October, it caught some of us with our pants down—or at least without anything up in the air cut to resonance on that frequency. A lot of eager beavers fired up 40-meter wires through their tuners and some of the guys even loaded up their tribanders in their hurry to try out the new megacycles.

I was prepared, sort of. I had a quarter-wave vertical up, arranged to work as a ground-plane antenna against the chain-link fence that is the ground system for my 160-meter and 80-meter inverted Ls. So, when the go-ahead came, I got in there and went, working out well enough to bag a few Europeans and even a VK3.

But I had troubles in the

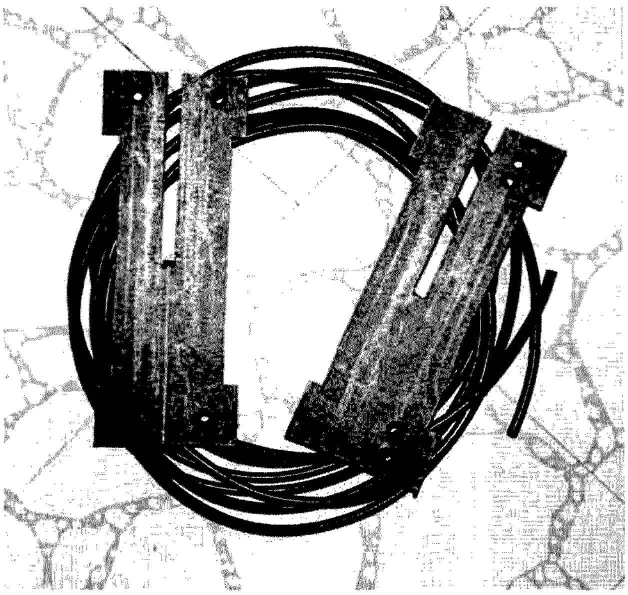

Photo A. Components of the Hanging Helix after sawing and drilling of the coil-form pieces from "waterproof" Masonite and their spraying with polyurethane to make them truly moisture repellent.

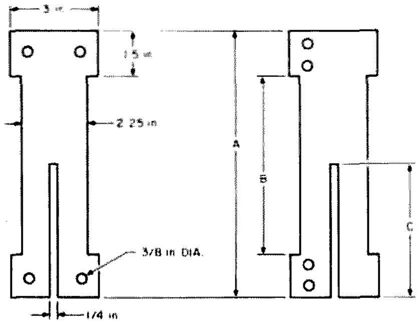

Fig 1. The Hanging Helix coil forms are identical except for the locations of the 3/8" holes. For 10 MHz, A, B, and C are 9", 6", and 4½" respectively; for 7 MHz, they are 13", 10", and 6½".

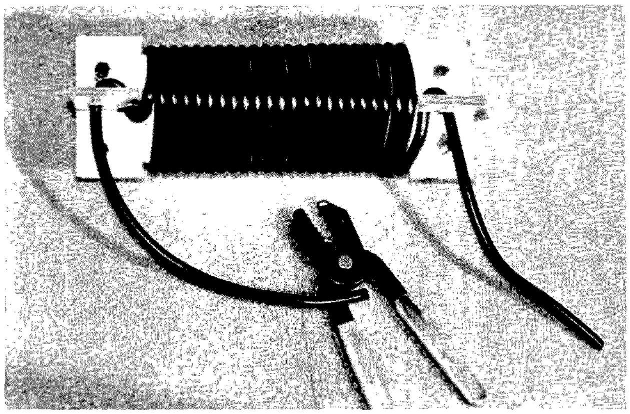

Photo B. The Hanging Helix after the quarter-wave matching transformer of RG-59/U has been wound onto the form.

form of NOISE. I can't speak for other QTHs, but mine is polluted with vertically-polarized man-made QRN that seemingly rises and falls on schedule. The rise, of course, always coincides with band openings that bring in skip signals to gladden the hearts of DXers. And the falls, naturally, always come when the only signals on the band are from just beyond the backyard.

That's the problem with vertical antennas, ground-plane or plain plane: They are noisy. And my new 30-meter GP was among the noisiest I have ever used. I don't know whether all line-leakage rf peaks around that frequency or whether it's a quirk peculiar to the man-made QRN in my neighborhood, but I do know that a delta loop, fed from the bottom and thus horizontally polarized, doesn't hear all that noise. Thus, it is unbelievable to switch to my Hanging Helix loop from the ground plane on even a relatively quiet day and hear signals come up out of the mud. And on a noisy day, the loop makes the difference between operating and deciding to watch the boob tube instead.

If you want to hear those signals-minus-mud in your own shack, you can duplicate my Hanging Helix delta loop easily and cheaply.

I used hardware-store number 14 house-wiring wire, the kind that comes with red, white, or black insulation for about 7 cents a foot, cut to the formula of 1005 divided by the frequency of interest. In my case, using 10.125 MHz as the new band's center frequency, the wire length came out to 99 feet, 3 inches.

Two insulators, threaded onto the wire and twisted into place at 33 feet, 1 inch and at 66 feet, 2 inches from the starting end, formed the base of the triangle that was to become my delta loop. Suspending it base up by those insulators from trees or whatever, high enough so the inverted triangle's apex cleared the ground, converted the tangle of wire into an embryonic antenna.

For the Hanging Helix that, together with the feedline, completes such an antenna, you will need two pieces of insulating material, each 9 inches long, 3 inches wide, and 1/4 inch thick. I used "waterproof" Masonite because I have scads of it left over from the era when I "finished" my basement. So-called "waterproof" plywood would do as well, I think, and Plexiglas™—the kind the stores stock for window-pane replacement—would probably be even better.

Each of the two pieces has a 3/8-inch strip 6 inches long cut off its two 9-inch edges, leaving a 1½-inch "T" at each end (see Fig. 1). Saw a 1/4-inch slot up the middle of each piece to the halfway point. Drill 3/8-inch holes near the four corners of one piece and a pair of same-size holes 3/4 of an inch apart vertically near the top and bottom of one side of the other piece. Now slide the slots together so that the two pieces become a single X-shaped coil form. Spray or brush the assembly with polyurethane or a similar waterproofing compound, applying it liberally to the sawed edges and the edges of the drilled holes to keep moisture out.

Cut the quarter-wave impedance-matching transformer, using the formula 234 divided by the frequency of interest times the velocity factor of the particular brand of RG-59/U you will use. I used a center frequency of 10.125 MHz for my 30-meter Hanging Helix which, using Radio Shack's published velocity factor of .75 for its foam coax, figured out to 17 feet, 4 inches.

Weave one end into the top hole of one of the coil form's vertical-hole pairs and out the hole just below it. Leave about 3 inches of cable sticking out for later connections. Close-wind the coax onto the form keeping it tight, the way you wound that very first coil when you were making your very first receiver or whatever. An easy way is to clamp the far end of the cable in a vise or the hinge crack of a door and walk towards it as you turn the form.

You will find that the cable and the coil-form space on which you are winding it will come out even if you stick to the dimensions given and are making it for the 30-meter band. If it's for 40 meters, scale the coil-form pieces up to 13 inches with 10 inches of winding room to accommodate the greater length of cable required by a quarter-wave transformer for that band.

Finish the device by weaving the end of the winding

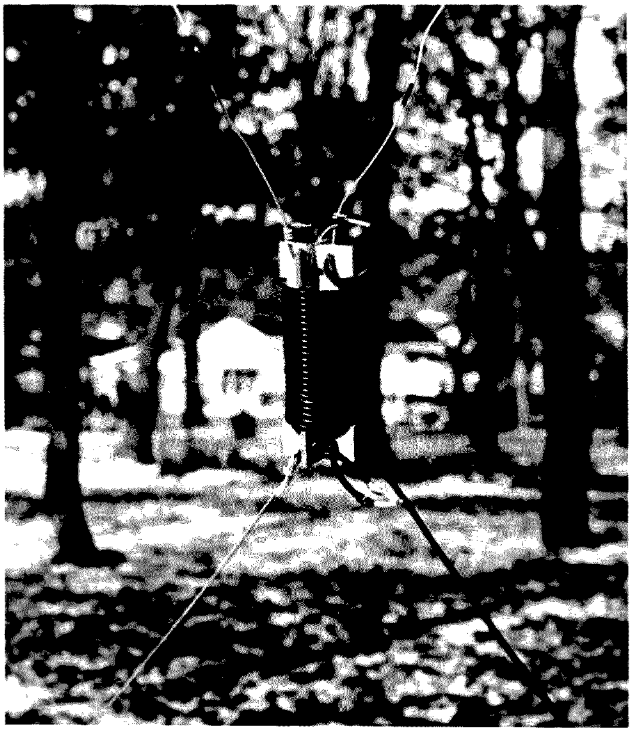

Photo C. The Helix hanging from the delta loop, the antenna wires and feedline attached but not yet taped.

into the hole of the vertical pair farthest from the top of the form and then through the top hole, pulling it tight to anchor it. Remove about two inches of the insulating jacket from each end of the coax, comb out the shield braid, twist it into a stranded wire, and remove about 3/4 inch of insulation from the center conductor.

Now take the whole works outside, feed the apex-end wires of the embryonic delta loop into the corner holes at one end of the form, twist each wire around itself to anchor it, strip back about 3/4 inch of insulation from each, and solder one wire to the center conductor of the coax and the other to its shield.

Push one end of your 50-Ohm feedline into one of the corner holes at the bottom end of the Hanging Helix, then through the other hole, and pull it tight to anchor it, leaving enough loose end to make your connections. Solder its center conductor to the center conductor of the coiled cable, solder the shield braids together, tape to prevent moisture entry, and your Hanging Helix delta loop is ready to pump rf into and out of the atmosphere.

Like any other antenna, this one follows the old "the higher the better" rule of thumb. But even with the feedpoint barely clearing the ground, you'll get out. Mine is about 10 feet up, and I prevent excessive wind sway by tying a light nylon anchor line between the coil form and a brick lying on the ground beneath it.

My in-line swr meter reads a flat 1 to 1 across the 30-meter band and well above and below it. My noisy reception is gone. My signals get out and I work what I hear. The Hanging Helix went up about two weeks after the new band was opened to us and has been in use for about six weeks as of this writing. In that time, my TS-830S, running barefoot, has racked up 18 countries for me despite sparse operating hours. I need only Asia for WAC on 10 MHz, and I'm told the band is full of workable Js in the early-morning hours. I wouldn't know, though, because I'm a devout sleepyhead.

That's all I can tell you except to warn you against locating two such antennas side by side or overlapping each other. I learned the hard way that adjacent 30-meter and 40-meter loops interact so that pruning one detunes the other. If they are hung concentrically, however, the 30-meter loop within the 40-meter loop with the wires spaced reasonably equidistantly around the perimeters, such interaction is minimized or eliminated. If you use this arrangement, you'll find that running the 30-meter Hanging Helix feedline down past the 40-meter Hanging Helix and taping it to the 40-meter feedline won't affect tuning or degrade the performance of either antenna.

That's the story, except for an apology for its title, which isn't quite accurate. In the first place, the new band isn't exactly centered on 10 MHz, and it has an FCC-ordered hole in it—a frequency "window" that is taboo to American hams. And, in the second place, I paid $7 for the antenna wire at my local hardware store, $2.80 at Radio Shack for the RG-59/U matching cable, and had the feedline, the Masonite, and a can of polyurethane on hand. But I also paid sales taxes of 28 cents for the wire and 11 cents for the coax.

I hope you'll forgive me for my untruthfulness, however, because such strict accuracy as "Build a 10.1-to-10.09- and 10.015-to-10.15-MHz Antenna for $10.19" would make a rotten title. ■

Photo D. The author tying on light nylon anchor line before hauling the delta loop skyward. At K9AZC, the Helix hangs about 10 feet off the ground, with excessive wind sway prevented by the "anchor," a brick lying on the ground beneath the antenna.

Slaughter's Sway-Bar Forest

Are trees an antenna hindrance? Or are they the means to the best antenna collection you ever had? It just depends on your outlook.

Antenna farms are nice, but not many of us have the space, the time, the money, or the inclination to be antenna farmers. Antenna orchards, on the other hand, are within the reach of every ham with a chunk of property under his control on which God has made some trees.

I am an antenna orchardist, and I find it rewarding.

I have wire antennas for 160, for 80, and for 40 meters strung up in my trees. They don't have the gain nor the directivity of my triband yagi, which is atop a conventional tower like everybody else's, but they do get out, they do allow me to copy my contacts, and they give me what most of us call all-band capability.

My lot is full of 50-foot, 60-foot, and even 70-foot oak, maple, and locust trees that in times past I begrudged yard space because three seasons of the year they make my tribander look into heavy masses of foliage in three directions. Now, however, I am happy with the trees, because some of them serve as towers for my wire antennas as well as giving shade for the lawn and sanctuary for squirrels and birds.

I have a length of nylon rope strung between two of them that are around 100 feet apart. From it hang the vertical portion of an inverted L cut for 1,840 kHz (the horizontal section of which runs along the support rope), another inverted L pruned for 3,750 kHz, a quarter-wave vertical wire cut for 7,050 kHz, and a delta loop (the resonant frequency of which centers on 7,150 kHz).

The suspension rope and, therefore, the top ends of all except the 40-meter vertical are about 60 feet up. The bottom ends of the vertical and the Ls are fed against a ground system that consists of the top pipe of a five-foot-high chain-link fence. The

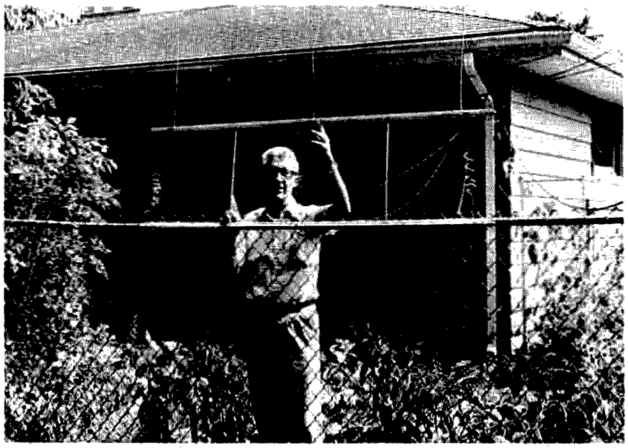

Photo A. Because trees bow and curtsy in the wind, and because vertical wires suspended from them thus dance up and down, some sort of flexible bottom-end tie-down is needed if an antenna orchard is to survive heavy gusts. I devised a "sway bar" system to beat the wind. Here, I'm checking its position. It's a five-foot fiberglass fence post tied with two screen-door springs to another such post strapped to the top pipe of a chain-link fence. The springs stretch and contract in the wind, maintaining tension on the vertical wires. The spiral pigtails wound into the antenna elements allow them to flex as the sway bar moves up and down.

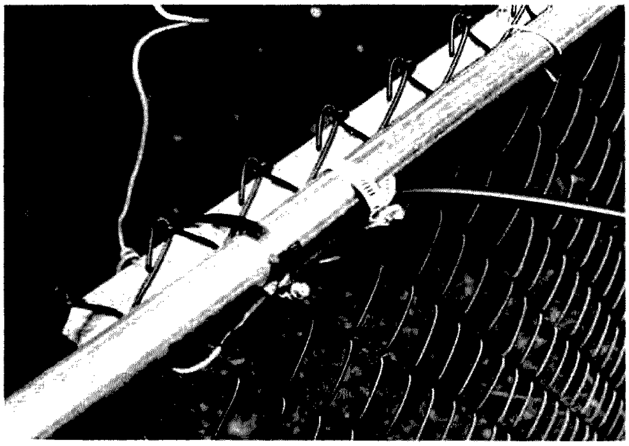

Photo B. Each of the antennas in my orchard is fed with a separate coax feedline. One of them is shown here. The left-hand hose clamp fastens both the fiberglass fence-post insulator to the top pipe of the chain-link fence that is my ground system and the coax braid to the grounding pipe. The right-hand clamp provides strain relief to eliminate pull on the grounding connection and the joint between the feedline and the antenna element. The first half-turn of the pigtail coil wound in the element between the insulator and the sway bar is visible at the upper left.

delta-loop feedpoint dangles about 12 feet above ground, connected to a homemade triangular insulator fashioned from Plexiglas™ that supports a commercial balun salvaged from a now-forgotten earlier antenna. A length of polypropylene rope tied to a brick resting on the ground keeps it from swinging in the wind.

The top of the 40-meter vertical wire ends in an insulator to which is tied a length of polypropylene line just long enough to suspend the antenna's bottom end at the grounding pipe.

I have a fiberglass electric fence post, one of those triangular jobs five feet long, clamped to the top pipe of my chain-link fence as a long insulator for all three of the vertical-wire antennas, and a second such post suspended about 18 inches above it as a "sway bar." Trees do sway in the wind, you know, bowing and curtsying to the breezes and even genuflecting to heavy gusts. The sway bar eliminates problems of too much wire tension when the wind lifts the treetops and too little when it sags them. It is tied to the insulator post with a pair of light screen-door springs. Thus, it can be pulled away from it, under tension, when the wind blows the treetops up, and can resume its original position, retrieving the slack, when the wind blows them down.

The sway bar is drilled with three holes for each of the three vertical wires it carries. Each wire is woven through the trio of holes to fasten it to the sway bar in a fixed position that can be adjusted up or down and locked in place by pulling the wire taut.

Each of the vertical wires is allowed about 18 inches of extra slack between the sway bar and the insulating post. The excess is wound into pigtail coils that lengthen and shorten as the wind moves the sway bar up and down. The vertical movement and flexing is thus confined to these flexible pigtails, and there is, therefore, no wind stress on the feedline connection to the antenna wires and no flexing of the solder joints.

The jackets on the separate 50-Ohm coax feedlines for the verticals are cut back about two inches, an inch or so of braid is uncombed and folded back over the uncombed section, and that portion of each feedline is squeeze-grounded to the top pipe of the chain-link fence with a hose clamp. A second clamp provides strain relief for each. The antenna wires are soldered to the center conductors of their respective feedlines and the joints are insulated with heat-shrink tubing.

I match the delta loop's impedance of about 100 Ohms with a quarter wavelength of 72-Ohm RG-59 between the 1-to-1 50-Ohm balun and the feedline.

All of the feedlines, together with the coax from my tribander, go into my garage where I have a remotely controlled five-antenna coax switch, wall-mounted, whose selector control is at my operating desk in the basement shack. A single run of RG-8/U connects my TS-830S and/or my Yaesu linear to any of the antennas at the turn of the selector-switch control knob.

None of the antennas in my orchard is either exotic or sophisticated, obviously. But all of them work well.

The delta loop is cut to frequency using the formula 1005/frequency in megahertz. It is a 140.5-foot length of #14 house-wiring wire, insulated with neoprene and formed into an approximately equilateral triangle a bit over 46 feet on a side, fed at the open bottom. That makes it horizontally polarized. Running roughly north and south, it displays little directivity and seems to work equally well into Europe, South America, Alaska, and Hawaii.

The 40-meter vertical is seldom used since the delta loop consistently provides better signal reports and better reception. But it's there for comparison purposes, and if I ever need it—for whatever reason.

The 80-meter inverted L, likewise, is seldom used, simply because I don't often get on either 75 or 80.

But the 160-meter inverted L is frequently pressed into service and, working against the chain-link-fence ground system, gets out remarkably well. It, like the 80-meter inverted L and the 40-meter vertical, also is #14 neoprene-insulated house-wiring wire. All three are cut from the quarter-wave formula, 234/frequency in megahertz. The 160-meter wire is 127 feet long, the 80-meter wire is 62.4 feet long, and the 40-meter wire is 33.2 feet in length.

Getting them up into the trees was no problem at all. Using a slingshot borrowed from the junior op, I used an old spark plug as a projectile, tying to it monofilament fishing line feeding from the reel of a spinning rod laid on the grass beside me.

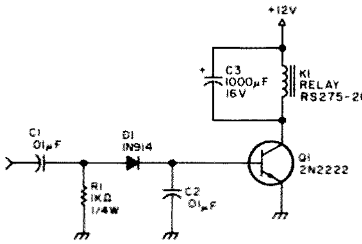
It took a few tries to get the spark plug over the selected branches, but pulling a light line into the treetops with the fishing line was simple enough, and then hauling the heavier nylon rope up as a permanent suspension line was child's play. It is long enough so that I can lower the center section all the way to the ground, tie antennas to it, and haul it—and them—up to the sky.

That's the story of my antenna orchard. If you can afford a full-scale antenna farm, go to it and happy acres, friend. But if you can't and have a few trees around, you might try orcharding. I think you'd like it. ■

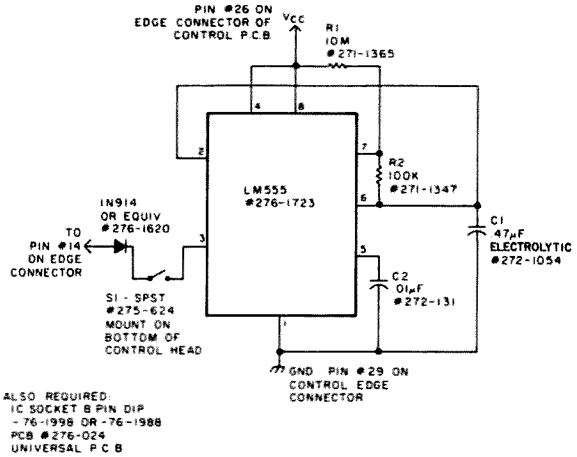
CIRCUITS

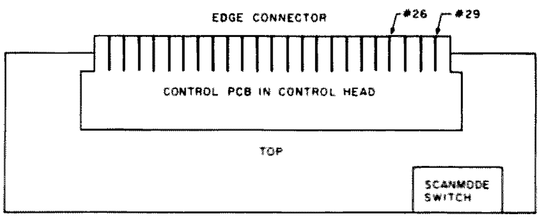
Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

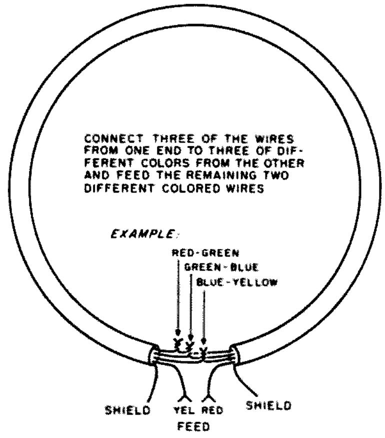


RF-ACTUATED RELAY: Here's a simple circuit to add automatic antenna switching to your home-brew power amplifier. This relay will key with less than 150 mW of drive on 2 meters.—Don Bohm WB0FLG, Sauk Rapids MN.





SCANNING RESUME FOR THE AZDEN PCS-2000: When scanning, the Azden 2000 will lock on a busy channel until the carrier drops, unless this modification is added. The 555 is wired as an astable, with three connections to the control-head PC-board edge connector: pin 14, the SQC line running from the discriminator section to the scanning control logic section; pin 26, which provides 13.8 V to the circuit; and pin 29, which is the ground. The time duration is determined by the resistance and capacitance values; the values given will allow the Azden to resume scanning after five seconds. By wiring the circuit on an 8-pin DIP socket, you will be able to mount it in the control head of the radio.—Kurt R. Fritsch WA3TOY, Glen Burnie MD.



SIMPLIFIED LOOP WINDING: A recent article described the construction and use of shielded loops for receiving under noisy conditions, but the author deplored the difficulty of sliding multiple turns through a shield. The easy way is to use shielded telephone cable. One standard form of cable has four wires coded yellow, red, green, and black, surrounded by an aluminum foil shield with a bare wire running under it. Just form the loop to whatever size is required, connect three of the wires from one end to three of a different color from the other end, and feed the two remaining wires.—William Bruce Cameron WA4UZM, Temple Terrace FL.

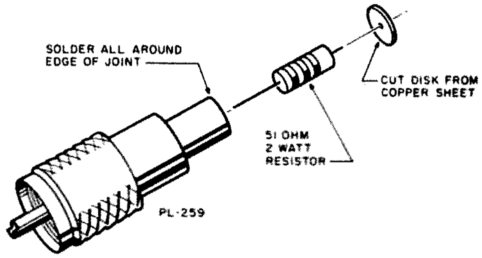


Fig. 1.

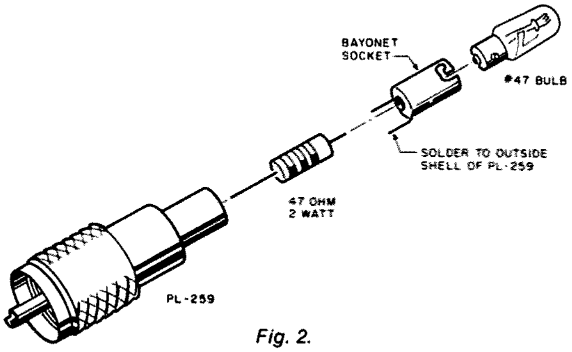

Fig. 2.

TWO VHF DUMMY LOADS: Fig. 1 shows a simple dummy load useful for frequencies at least as high as 220 MHz. It is a well-shielded load and can handle up to 5 W intermittently. To make the dummy load, insert a 51-Ohm, 2-W carbon resistor into a PL-259 connector. Solder one end of the resistor to the center conductor, making sure that the body of the resistor is completely inside the barrel of the connector and that only the resistor's lead sticks out past the body of the PL-259. Cut a disk out of copper or brass sheet (shim stock works well—even a penny can be used), drill a hole in the center, and slip it over the resistor lead, fitting it snugly against the end of the connector. Solder all around the edge of the disk and the lead in the center. File off the excess disk material. Fig. 2 shows a modified version that will give a visual indication of relative rf power as well as provide a 50-Ohm load. The dummy will handle up to 5 W intermittently and will indicate output as low as ¼ W.—Craig Crichton K7UKW, The Dalles OR.

The Phase-Shift Oscillator Goes Hollywood

This circuit can be the star of your audio designs. All it needs is a tweak here and a taper there.

Curtis C. Goodson
Av. Francisco Glicerio 467
Apartment 502
13100 Campinas, Sao Paulo
Brazil

The phase-shift oscillator is noted for good stability and a clean sine wave. It also uses a very simple circuit. Hence, many hams attempt to use it when an audio oscillator is needed, only to discover that "it won't oscillate." The beta of the transistor is most often blamed for the difficulty. Although it is true that a rather high beta is needed to overcome the loss in the phase-shift network, with today's transistors a high beta is easy to find and still "the shiftless thing won't oscillate."

Most often the phase-shift network is taken from tube circuitry without being adapted to transistors. In the tube circuit, the network is fed from the high impedance plate and terminated in the even higher impedance of the tube's grid. When a bipolar transistor is substituted, the network is fed from a fairly high impedance but feeds into the low impedance of the base. Therefore, a high-to-low impedance transformation should be included in the network design. Tapering the values of the network components will do it. Make R_{out} about ⅓ of R_{mid} and R_{mid} about ⅓ of R_{in}. (See Fig. 1.) Then, to keep the phase shift at 180°, make the RC products of each section the same: $R_{out} \times C_{out}$ equal to $R_{mid} \times C_{mid}$ and to $R_{in} \times C_{in}$.

In the circuit in Fig. 1, the collector load resistor of 33k Ohms serves as R_{in}, so R_{mid} is about ⅓ of that, or 10k Ohms, and R_{out} is ⅓ of R_{mid}, or 3.3k Ohms. To keep the RC products equal, C_{mid} is $3 \times C_{in}$ and C_{out} is $3 \times C_{mid}$. The approximate frequency of oscillation is found by the formula: $f = 1/11RC$. For the values in the example, the frequency will be about 600 Hz.

The resistor from collector to base biases the transistor and should be chosen for best waveform and output. A value from one to one and a half megohms will be about right. The output is taken from the collector, but be careful not to load down the high impedance of the network.

If those "computer surplus" transistors just do not have enough gain, use a pair of them in a Darlington connection, as shown in Fig. 2. You'll probably have so much gain that it won't be necessary to taper the network values.

Minor frequency adjustments can be made by altering just one or two of the resistors or condensers. The 500k-Ohm potentiometer is adjusted for best waveform. A double-pole switch can be inserted at x-x to select networks for different frequencies, but the pot may need readjusting each time. Since transistors are so cheap, why not build a separate oscillator for each frequency? No transistors are specified since almost anything will work. ■

Build the Harmonic Zapper

When the TV starts sounding like Donald Duck, you need this 20-meter trap.

John Labaj W2YW
12 Park Place
Elsmere NY 12054

When I got back on the air after a long layoff, I ran into some really severe interference problems. I interfered with every working television channel on all television sets in the house. My signals rode in on the Hammond organ, jammed the telephones, and made most of the lights in the house flicker.

Over the years I cleared the lights, organ, and telephone lines of all interference and reduced the TVI to where I could operate with full power on forty meters with just a faint trace of interference on channel six. It was too slight to be objectionable. The other channels were perfectly clear.

However, when I tried to operate on twenty or higher, channel six would be wiped out. Being of a lower order, the amateur harmonics from the higher bands were stronger. No attempt at a cure seemed to have any effect. Low-pass filters were useless. They absorbed power and heated up or broke down. Reluctantly, I came to the conclusion that maybe I had reached the limit as to how much TVI I could eliminate. As a result, most of my operating was on forty.

One rainy Sunday when QRN made forty meters just about a total loss, I decided to make another attempt to lessen the TVI problem. Although I had tried an open-ended quarter-wave stub across the line, I decided that perhaps a combination of a shorted stub and an open stub would be more effective. The shorted stub, in series with the feedline, would represent a parallel tuned circuit and thus be a high impedance at the harmonic frequency. The open stub, across the line at the output end, would act as a coil and capacitor in series and would be a very low impedance at the harmonic frequency. They would have no effect on the operating frequency.

In very short order I had the trap made up. I installed it in the feedline and tuned the rig up on twenty meters. I set the keyboard up for automatic keying and went around the house checking channel six and other channels for TVI. Not a trace. In fact, reception was so clean that I went back to the shack to see if the transmitter was being keyed. It was.

I tried the other bands. Still no interference. I ran the transmitter for about fifteen minutes to give the trap a smoke test. The trap remained cold. Furthermore, the trap had made no noticeable change in the line current, the loading, or the tuning.

As a final test, I loaded up the amplifier (four 572Bs) heavy, raised the grid bias voltage to 250 volts, and increased the drive to 250 mA of grid current to really squirt out a lot of harmonic power. Still not a trace of TVI. The trap really was a killer.

Let me tell you how I built the harmonic killer. Bear in mind that this idea will work on other channels. You can even hook these traps up in tandem in case you have more than one trouble spot.

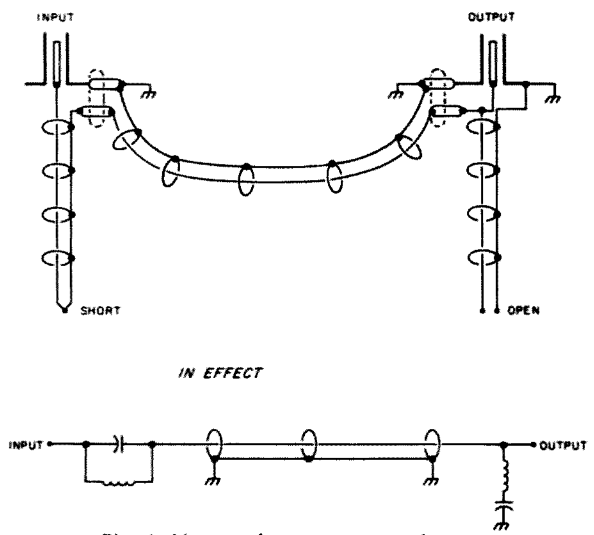

Fig. 1. Harmonic trap connections.

To cut the stubs to the right length, I used the familiar formula $L = (246 \times V)/F$, or $L = 246V/F$, where L is in feet, V is the velocity factor or the coaxial cable, and F is the frequency in megahertz.

Since I operate mostly in the low end of the bands, I selected 84.15 MHz as the target frequency. However, I later found out that the trap is effective over a broad range of frequencies. Using 84.15 gave me a stub length of 1.929 feet (about 23 and an eighth inches).

Here is a list of materials I used. Since it was a Sunday, I made do with what I could find around the shack. Also, I wasted no time or money running to the parts store. I do not consider this the ultimate in trap construction. Your ideas may be better, but this trap is easy to build and it works.

- Two 6-inch tomato cans. These are seven inches high and are free from your favorite restaurant or their rubbish pile. (I use them for storing parts.)
- Two SO-239 female coaxial cable fittings.
- Two tiepoints with one ground lug and one insulated lug.
- One plastic bottle or plastic container used for detergents or sour cream about 3 or 4 inches in diameter and about 6 inches high.
- Enough RG-8/U to make up the two stubs plus about 9 inches to connect the two SO-239 fittings together.
- A few nuts and bolts to put the pieces together.
- Some lacing twine or heavy string.
- Some fingernail polish—or something similar.

Using tin snips, cut one can down so that it is only about an inch and a half high. The other can requires no work. On the cut-down can, make some vertical cuts with the snips so that later on you can bend in the side and nest this can into the other can.

Mark a diameter on the bottom side of the can. Five-eighths in from each edge punch two five-eighths-inch holes to take the SO-239 fittings. Use an upside-down SO-239 fitting as a template and mark and drill two mounting holes for each fitting.

Take the tiepoints and enlarge the holes in the lugs and also the hole in the foot (ground lug) by putting the tip of your needle-nose pliers in the holes and turning.

While mounting the SO-239 connectors, bolt a tiepoint (using the same bolt) at each connector.

Lay a piece of coax along the edge between the two SO-239 connectors so that you can judge how to cut and prepare the ends. When you have the short coax cut and prepared, connect the inner conductor to the insulated lug of a tiepoint using the lower hole. You may have to file the wires a little to fit in the hole. Connect the shield which you twisted into a pigtail to the grounded lug. Solder both. The SO-239 connector at this side will be the input end and will go to the output of the transmitter.

At the other end of the short piece of coax, run the inner conductor (which you made about an inch longer) through the lower hole of the insulated lug and continue until you push the end into the solder hole of the SO-239 connector. Solder both. Solder the shield to the ground lug using the lower hole.

Prepare the plastic container by drilling several mounting holes in the bottom. Place them far enough away from the side so you can reach the bolts and nuts. Also drill a row of closely-spaced holes at all four quadrants of the container. These will be used to tie the coax to the form.

Center the plastic container between the two SO-239 connectors and mark the location of the two holes so that you can drill the bottom of the can and mount the plastic container.

To make the stubs, remove about an inch of the outer jacket from an end of coax. Unravel the shielding and twist it into a pigtail. Cut off about half an inch of insulation from the inner conductor. Since this is going to be the input of the trap, the high impedance side, shape the inner conductor and file to fit into the inner contact of the SO-239 fitting. The shielding braid is going to be part of a hot circuit, so it will connect to the insulated lug—the one where you already have connected the inner lead of the short coax. Solder both.

Inspect the connections to make sure there are no loose strands to short things out. Stretch the coax out and measure from where the shielding is formed into a pigtail along the coax for the proper distance plus a quarter of an inch for making the short between the shield and the inner conductor. Cut the coax. Strip off about a half inch of jacket, push the shielding back, and remove a quarter inch of insulation from the inner lead. Clean the wires, pull the shielding forward, twist it around the inner lead, and solder.

For the open-ended stub, the one in shunt with the line, prepare the ends as before. Connect the inner conductor to the insulated lug which already is connected to the center contact of the fitting. Connect the shielding which you formed into a pigtail to the grounded lug. Again measure off the right length, but do not allow a quarter inch for shorting the conductors together since this end will be open. Check the cut end to make sure there is good clearance between the shield and the inner conductor. Paint the end with fingernail polish.

To wind the stubs on the form, start with the stub that has the shield grounded since it will not be sensitive to capacity effect. Wind the stub around the form, lacing and tying it as you go along. Use a folded piece of #18 wire for a needle. If you cannot get your hands into the form, use long-nose pliers to thread the needle through the holes. Space the turns about two inches apart. When you have the one stub tied down, do the same with the other stub, winding and tying it between the other turns. The two stubs should be about an inch apart. Check all work.

Paint the joints, the nuts, and the knots with fingernail polish.

Nest the can on which the trap is assembled into the other can, pushing down as far and as evenly as it will go. You can either spot-solder the two cans together or use some tape to hold the assembly tight.

One last comment: After I got through admiring the trap, I fastened it to the tree holding up the dipole. I used a plastic pail for an umbrella.■

Parts List

5½'	Belden #8237 RG-8/U coaxial cable	$1.93
2	Amphenol-type SO-239 connectors	.80
6	8/32 half-inch plated bolts and nuts	.72
6	Washers—four lock-type, two flat	.12
2	Six-inch-diameter tin cans, 7" high*	N/C
1	Plastic container 3-4 inches in diameter and 6" high**	N/C
6'	Lacing or other sturdy twine or carpet thread.	N/C
	Elmer's Glue or fingernail polish. Small amount of solder.	N/C
	Total	$3.57

* Three-pound coffee can; restaurant-size tomato or mushroom cans are free from most restaurants for the asking.

** Soft drink, shampoo, instant tea, marshmallow whip, and many other items come in suitable bottles or containers.

The Anti-Gravity Antenna-Erection System

Now you can put your wire antennas as high as you want—maybe.

Joyce Kilmer once wrote:
I think that I shall never see
A poem as lovely as a tree.
But trees mean different things to different people. Personally, I can never visit a tropic island and see a home surrounded by tall coconut palms without mentally projecting an antenna farm onto those trees.

Early History

In 1948, when I moved into a house in Washington, DC, surrounded by trees, I was faced with the problem of erecting wire antennas without ever having acquired climbing skills. By 1950, I had begun to study how to use a bow and arrow to accomplish this, and by 1952, I was the author of a published article outlining problems and procedures.[1]

In seeking ways of getting a rope up over a tree limb, I immediately rejected any method which employed a pistol or other firearm as unsuitable for most civilian purposes. A group of techniques concerned with a slug, fishing sinker, rock, or ball attached to a line, thrown by means of a hand pitch, sling shot, or casting rod, were rejected after some early experimentation with a small rock on the end of a line. A problem would develop if the object came down over a limb with only a little line to spare and wrapped itself around this limb. On one occasion, it became evident that such an object, suspended over a sidewalk, constituted a real hazard; it was removed with the help of the Fire Department using a hook and ladder.

The choice narrowed down to a bow and arrow—the arrow, of course, being blunt-nosed. The idea was to fire a light line over a

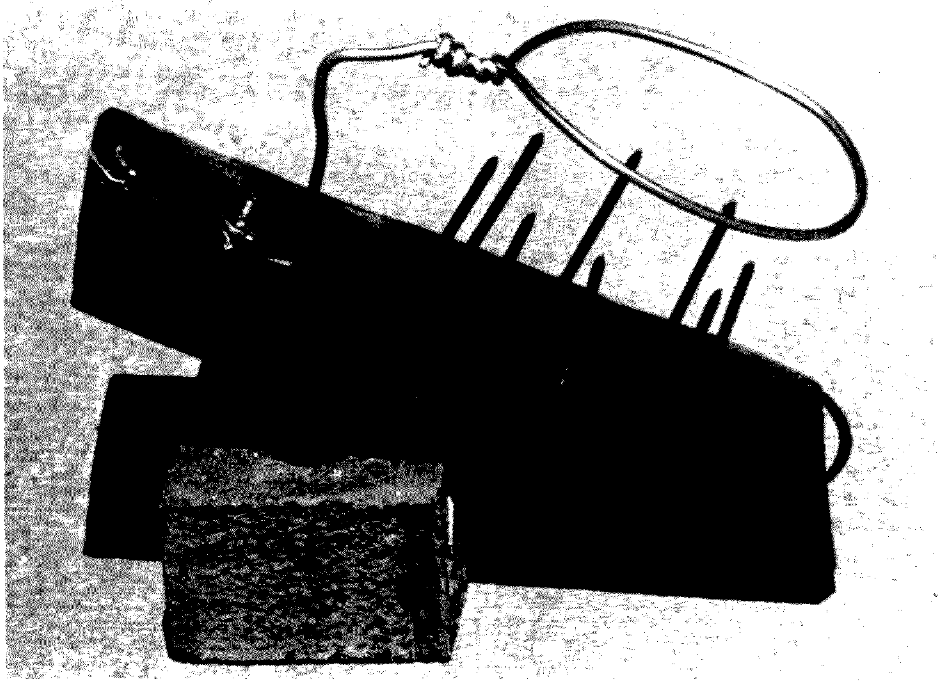

Photo A. Early open-end reel design, using nails and a guide ring.

branch, use it to pull a heavier line, and then follow with a rope. Those days, to ensure the least drag on the arrow, I used what was then known as Size A nylon thread as the initial line, followed by a string known to the trade as carpenters' chalk line. The chalk line was used to haul a 9.5 mm (3/8") rope. Since these lines, when pulled, tended to catch in small crevices and crotches, it was necessary that the junction between one line and the next be wrapped in a conical fashion with smooth waterproof tape, as shown in Fig. 1.

Fig. 1. Tapered line joint.

The arrow itself had to be just heavy enough to come down by its own weight, dragging the line after it. In those instances where the shot was terminated with the arrow suspended out of reach, a slight jiggling of the other end of the line sometimes was needed to make the arrow slide again. The arrow I finally chose was a straight section of 8 mm (5/16") wooden dowel, 66 cm (26") long. Tail fins made of tape were essential to keep the arrow from tumbling, three being used. I notched the tail end of the arrow to fit the bowstring. I made a notch near the tail; its purpose was to clinch the end of the line, which was knotted.

One of the most difficult maneuvers I ran into in the early days was that of getting the arrow to drop over a desired branch in a grove of trees. Sometimes the arrow would come down and drag the line over a branch of a tree farther away than the one intended. It was frequently possible, with care, to withdraw the line slowly, while jiggling at the same time, in such a manner that the arrow came back over the unwanted branch and fell again, pulling the line over the correct branch. Fig. 2 illustrates the case.

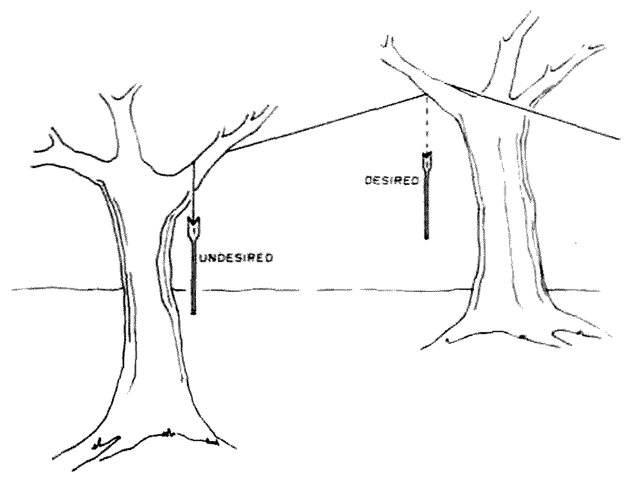

Fig. 2. Arrow falls in wrong tree.

Storing and launching the line required a special technique. Whether I was pitching a rock tied to a line or firing an arrow, letting the line lie in random fashion on the ground resulted in snagging on irregularities, blades of grass, and trash. My initial solution was suggested to me by an unknown Air Force enlisted man who happened to be browsing in the same sporting-goods store where I bought my first bow.

My first line-launcher system had eight large nails laid out in a circle, protruding through a small board so as to form a crude open-face reel. (Remember, this was before the time of spinning reels.) In making a shot, I set the reel on the ground and aimed it like an artillery piece, propping up the little board with a stone. In retrieving the line, I wound it back on the reel by hand, taking care not to gash my hand on the ends of the nails. Problems with occasional snagging of the line on those nail ends led me to devise a wire guard ring held to the board by means of a vertical section and a wing nut. Before retrieving the line, I would release the guard ring, which would then float on the line, sometimes getting tangled.

I was not the first to use the bow-and-arrow technique, apparently. Many years ago someone informed me that he had seen an earlier article in *CQ* magazine.

Later Developments

In later years, I decided to sacrifice some of the range available with a light nylon thread as the line so as to have a line strong enough to haul the final antenna rope, thus eliminating the need for an intermediate hauling line. I began using woven-nylon casting line of 20-pound test strength. Also, for Field Day operations, I found nylon parachute cord satisfactory for wire antennas supported by trees. I kept the same arrow specifications but found that two tail fins still provided stability. For suitcase portability, I made some shorter arrows.

One big improvement was my replacement for the open-face line launcher described above. For my new design, I fastened the top of a peanut-butter jar to a small board and then screwed the inverted jar into its lid. The outside of the jar became the open-face reel. Initially, I used a guard ring as before. Finally I resorted to an eyelet suspended above the jar on a dowel stick mounted far enough away from the jar so as not to interfere with rewinding, so that nothing would have to be removed for retrieval of the line.

I call this line launcher, illustrated in Fig. 3, the PBJL (peanut-butter-jar launcher) and advise prospective builders to eat the peanut butter before assembling the device.

For portable operation, I found it desirable for everything to be short enough to fit into a standard suitcase. I had previously designed a vertical whip antenna using a fiberglass mast in 61-cm (2-foot) sections, each section being socketed to the next by means of drilled wooden dowel segments cemented to the sections. By plugging two of these mast sections together, I have a 122-cm (4-foot) archery bow. A nylon string of the right length fastened at each end to eyelets on wooden caps drilled for the fiberglass rod diameter provides me with an instant portable bow ready for use. Fig. 4 shows the components.

I found that the mast for an all-terrain vehicle safety-warning pennant is an excellent low-cost source of fiberglass stock. The type purchased was The Detector, Columbia Products Co. (subsidiary of Shakespeare Co.), PO Box 4470, Columbia SC 29240.

Noticing the improvements in fishing reels over the years, I thought it would be interesting to see what a spinning reel would do for storing and releasing the line, i.e., as a launcher. I had been reluctant to make any tests, fearing that a monofilament line would be too springy in contrast to a woven casting line. Finally, however, a note in *QST*[2] indicated that Larry W3MSN was having success with a

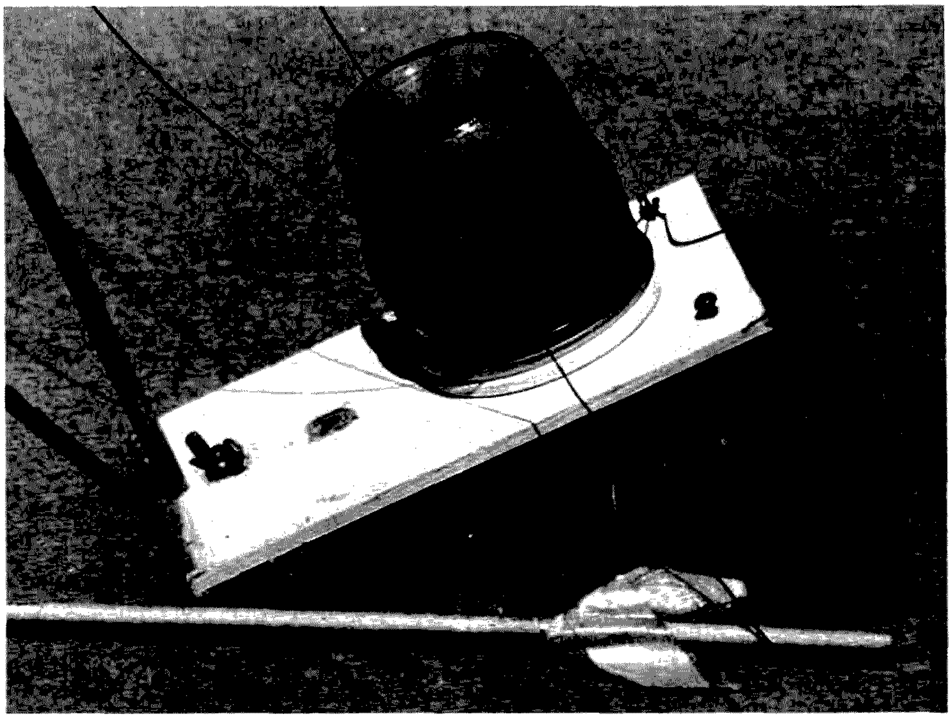

Photo B. Close-up of PBJL line launcher.

closed-face spinning reel, Zebco 202 (erroneously reported as Zebra 202). In looking over the merchandise at a local sporting-goods store, I noted that the Zebco 202 was their least expensive reel, so there was every reason to buy one.

I tried the Zebco mounted on a piece of PVC pipe inserted in a small flagpole bracket and aimed in the desired direction. I used the 8-pound monofilament line which came with the reel. The range was rather good, but, as apparently is true with all spinning reels, the line began to bind on the edge of the spool after a certain amount had come off.

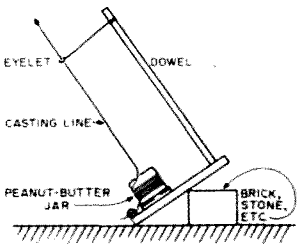

Fig. 3. PBJL launcher.

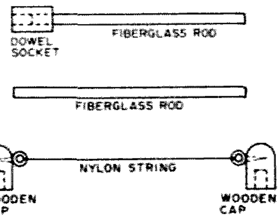

Fig. 4. Portable bow components.

There was a more serious problem, however. For low-angle shots, results were good. Shooting at high angles, however, the falling arrow permitted the line to fall without tension, a situation which apparently does not occur in casting. The monofilament line tangled hopelessly as it approached the ground. Limp, woven-nylon casting line would have been vastly better in this regard. However, I now began to realize that a spool with straight sides actually requires a springy line for the line to be able to hurdle these straight sides in coming off a spinning reel.

Then I made a compensating discovery. It is possible to purchase monofilament lines with different degrees of springiness. The kind with the trade name Trilene is sold in three grades of stiffness. I bought a roll of 8-pound Trilene XL, the least stiff. I followed the advice of a salesman—who said that only the top 3.2 mm (1/8 inch) or so of line would come off a spool without binding—and filled most of the reel with old woven casting line, depositing the monofilament line above this. Success was instant.

Since I was still interested in a line heavy enough for senior citizens' eyes to see and heavy enough to haul up a strong rope, I did not give up on the idea of a 20-pound line. So my next purchase was a roll of XL in the 20-pound strength. This was too heavy to use in the small Zebco 202, so I bought an Olympic ES-2 skirted-spool, open-face spinning reel. This reel is capable of handling heavier lines, and the side of the spool against which the departing line rubs is tapered so as to lessen the binding mentioned above.

I mounted the reel on PVC tubing inserted in a flagpole bracket, as with the previous reel. With an open-face reel, however, it was necessary to guide the line by means of an eyelet mounted above the reel on the tubing as in the case of a casting rod.

To my disappointment, using the 20-pound XL line with the Olympic reel resulted in a tangled mess on the lawn, in which a cherry tree, the neighbor's dog, and I were temporarily imprisoned. Evidently, even the XL grade was too springy in the 20-pound size.

But I had "one more string to my bow," so to speak. Considering my previous successes with the very limp 20-pound woven-nylon casting line, the next and last step was to try this line with the Olympic reel. Success was achieved, but the results were not as good as with the PBJL launcher.

Conclusions

Results of tests are summarized roughly as follows:

1) The Zebco 202 wound with 8-pound Trilene XL monofilament line gave about 5% greater range than my PBJL with 20-pound woven-nylon casting line.

2) The Olympic ES-2 with the 20-pound woven line was about 15% worse than the PBJL with similar line.

Greatest range and some reliability came with the Zebco 202 closed-face reel filled with old line and then wound with 8-pound Trilene XL. However, the 8-pound line is hard for many people to see and might still be more springy than desired, besides not being as strong as might be desired for hauling a rope over a branch. It appears that the PBJL with 20-pound woven line was the better

choice. However, the Zebco 202 combination is the most portable, whereas the Olympic ES-2 combination is less fragile in transportation than the PBJL and affords faster line retrieval.

As to approximate heights possible, the following was achieved:

1) 28-pound bow and light nylon thread (in 1951): 27 m (90 ft.).

2) 30-pound bow with PBJL and 20-pound woven casting line: 20 m (65 ft.).

3) Portable bow described in the text with PBJL and 20-pound woven line: 9-12 m (30-40 ft.).

Elsewhere, in Oregon, K7MKG has been using a modern compound bow. Jack stated in a QSO that he reaches heights in excess of 30 m (100 ft.) with monofilament line which he says should not be in excess of 10 pounds in rating, agreeing with my observations noted earlier in the text.

In a subsequent letter, Jack wrote: "I might add that I am using a large saltwater open-face reel, a Shakespeare No. 2090. I attach it to a short piece of 1/2" pipe with a hose clamp. I then stick the pipe in the ground with the reel aimed at the treetop. I have little trouble with 8-pound Stren. The large reel is probably an advantage."

Relative to reliability, a follow-up by mail on results obtained by W3MSN[2] revealed that Larry did sometimes experience problems of debris remaining in trees, which illustrates the need for blunt-nosed arrows. Although in five successive Field Day operations ending in 1979, the Boulder Amateur Radio Club archers scored only one loss of an arrow (in an irrigation ditch) and did not decorate any trees with fishing line, still my own occasional bad experiences indicate that skill and caution are needed, even to the extent of having bystanders keep a safe distance in the event that the line from the launcher snags on one end of the bow.

Here it becomes appropriate to quote Henry Wadsworth Longfellow. In "The Arrow and the Song," he wrote:

I shot an arrow into the air.
It fell to earth I knew not where. . .

In today's bedroom communities and even among the Rocky Mountain evergreens of Boulder's public park on Mt. Flagstaff, where Field Days are sometimes held, Longfellow would be considered irresponsible.

Later in the poem, Longfellow told about finding the arrow "long, long afterward in an oak." Luckily, for irresponsible-but-sensitive Longfellow, the recipient was only an oak tree. Another case for blunt-nosed arrows—unless you're out deer hunting—in season, of course.

While wishing you all good luck with your archery, let me once again turn to Joyce Kilmer's poem quoted in the beginning. He described:

A tree that may in summer wear
A nest of robins in her hair.

When we utilize antenna archery, let's not replace that "nest of robins" with a "mess of rope ends," remembering that Kilmer also wrote:

Only God can make a tree. ■

Your Own Beam-Bruiser

Muscle your beam around from anywhere with this local control box. It's perfect for serious tower work.

For those of you who do more than a casual amount of work on your tower and/or beam, control of the beam heading from the tower could be an advantage. Such was the case at my QTH, and it prompted the local-control unit described here for my HAM IV Rotator System (see Fig. 1). Modifications to existing equipment are made in the HAM IV control unit and should not require drilling any holes if you are careful and use your imagination. Access to the individual wires in the rotator-control cable at the base of the tower also will be necessary.

The local-control unit will duplicate all the functions of the remote-control unit except for power control and meter indication. Safety is designed into the circuit so that, when under local control, the remote-control unit has no effect on the rotator. This prevents someone in the shack from inadvertently moving the beam while you are working on it. The local-control unit may be housed in a weatherproof box or stored in a protected location.

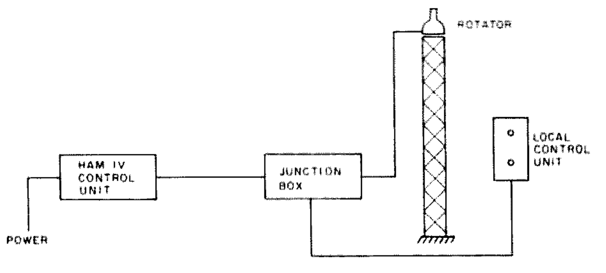

Fig. 1. Beam rotator system showing added local-control unit. Rotator unit on tower requires no modification, nor does cable run up tower.

Modification of Remote-Control Unit

Fig. 2 shows the schematic of the modified HAM IV control unit. The contacts of relay K1 added to the chassis carry 120 V ac at about 1 Ampere and must be accordingly rated. I used a small surplus unit and wired its DPDT contacts in a double-break configuration. Coil voltage should be rated at 12-24 V dc and less than 100 mA. Appropriate series resistance can be used with a lower voltage coil, but should be avoided because of the higher actuation currents.

To simplify matters, the following procedure is suggested and may save you from chasing wiring around the chassis to determine where connections are most easily made. However, I would suggest that you double-check your wiring to make sure that production variations don't exist between my unit and yours.

- Before starting, pull the power plug! Line voltage is present on several exposed points inside the unit.
- Remove the top and bottom covers by loosening the eight screws in the sides of the unit.
- Mount the relay to the chassis. There are several unused holes in the chassis that could be used, or you can bend up an aluminum bracket.
- Unsolder the heavy transformer-secondary wire from terminal 1 of the terminal strip on the rear apron and connect it to the grounding lug on the chassis just below the terminal strip.
- Disconnect both ends of the short jumper between terminal 1 and ground and discard the jumper.
- Connect a wire from the cathode (banded end) of diode CR1 on the PC board behind the meter to one coil terminal of the relay.
- Connect the other coil terminal to terminal 1 on the rear-apron terminal strip.
- Connect the normally-open relay contacts across the terminals of BRAKE RELEASE microswitch S3. This is the center switch in the three-switch stack near the front panel. Use #18 AWG wire.
- Check all connections, dress the added wires to prevent interference or chafing later, and replace the top and bottom cover sections.

This completes the remote-control-unit modifications.

Construction of Local-Control Unit

Fig. 3 shows details of the local-control unit. If the unit

is to be stored in an unprotected location, a weatherproof enclosure should be used to house the components. Otherwise, a standard minibox can be used. Construction is straightforward, the only precaution being in the selection of the DIRECTION (S2) and SAFETY (S3) switches. These carry the motor current, which is about 2.5 A ac, and should be rated accordingly. BRAKE switch S1 has only to carry the brake-control relay current. Rotary switches for S2 and S3 are not recommended, as they will probably not carry the load.

The indicator lamp shown in Fig. 3 is optional but is recommended to remind you that you have the brake released (energized). The ac voltage across the brake line (terminals 1 and 2 of the rotator) is about 30 V ac. By using the diode in series with the lamp, the voltage is effectively halved to the lamp, thereby reducing the power-rating requirements of the series resistor. Measure the voltage between X and Y on your unit and insert the appropriate resistor. Calculate its value using Ohm's Law and the rated current/voltage specs of the lamp you are using.

One more wire will be needed in the cable out to the junction box at the base of the tower to allow actuation of the brake-control relay in the remote-control unit. If you have spares in the existing cable, fine. If not, lay a length of ordinary zip-cord, field-telephone wire, or even a single strand of #20 AWG along the existing cable run to the junction box near the tower base. The cable run up the tower to the rotator is left as is.

Close inspection of the circuit might suggest that perhaps the extra wire isn't needed after all. By moving the power-transformer secondary from terminal 1 of the control unit to the chassis (where it was electrically connected anyway), we freed up terminal 1 so it could be used to energize the relay from the local-control unit. If our station is prudently wired, then everything will be grounded. Further, if the tower is grounded to the same point as the station ground, then theoretically we could use this ground line as the return circuit for the motor and brake in the rotator, and use terminal 1 on the remote-control unit for relay control—we wouldn't have to add anything to the control cable. *Don't do this!* That ground line is there for safety reasons and must not be used as a current-carrying conductor. Use the circuit shown here and you will retain grounding protection.

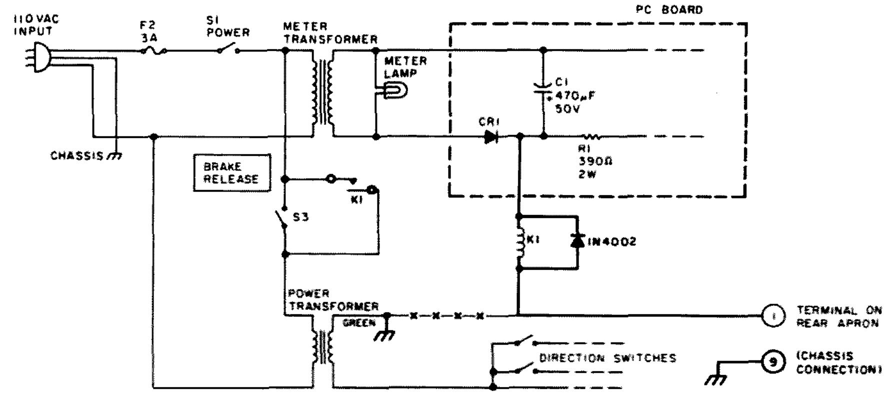

Fig. 2. HAM IV control-unit modification. Heavy lines show circuit changes and added parts. See text for relay information.

Junction-Box Details

I would strongly recommend the use of some sort of junction box (see Fig. 4) to make the connections between the local and remote unit and the rotator. Cut the control cable only after careful examination of junction-box placement and cable run. Locate the box out of the weather if possible. If not, use a weatherproof enclosure. A simple, albeit not elegant, method is to drive a length of 1 × 4 board in the ground to attach the terminal strip and hang a plastic trash can upside down on the board. There would be room inside for the terminal strip and the local-control unit.

Final Checkout and Operation

Do the following step-by-step checkout procedure to make sure that all connections are correct.

1. Set the local-control-unit switches to the following positions: SAFETY (S3)—Remote, DIRECTION (S2)—Stop, and BRAKE (S1)—Set.

2. Plug in the HAM IV remote-control unit and turn the power switch on. The light in the meter should illuminate and neither the brake nor the motor in the rotator should be energized.

3. Operate the unit and verify normal operation, checking all functions. If there is any difference between the "before" and "after" operation, shut down the unit immediately and check your wiring.

4. Now, leave the power switch on, go out to the tower, and set the SAFETY switch to the Local position. Nothing should happen. This switch disconnects the motor-control lines from the HAM IV control unit to prevent inadvertent operation while you are working on the beam.

5. Move the BRAKE switch to Release. You should hear the brake sole-

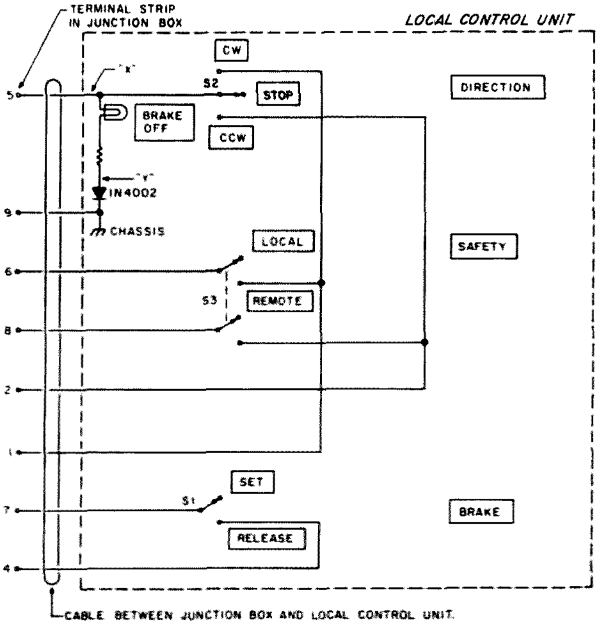

Fig. 3. Local-control unit schematic. See text for explanation of X and Y. See Fig. 4 for conductor sizes in local cable.

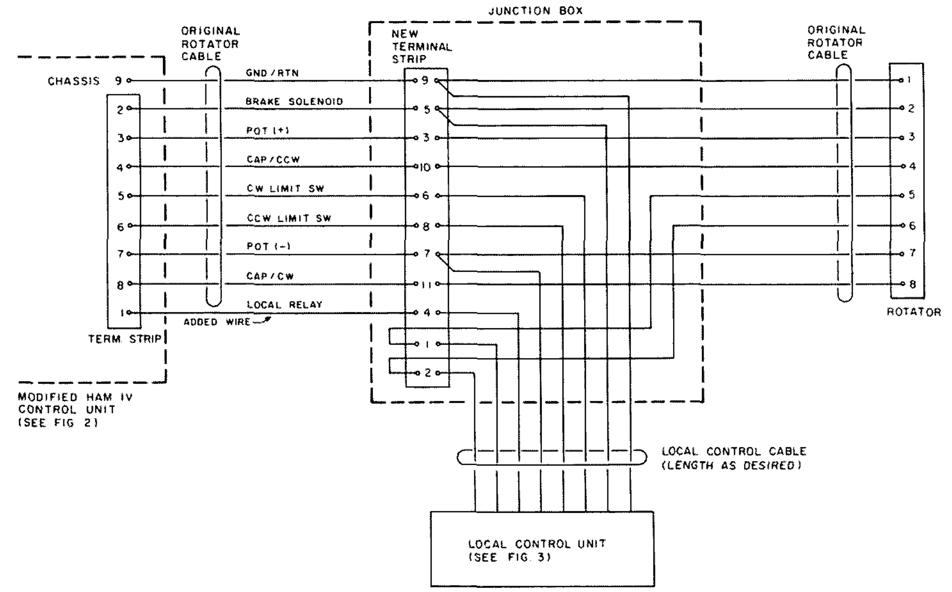

Fig. 4. Junction box and overall cabling. If added local-control cable plus existing cable lengths total less than 125 feet, use #22 wire in local cable. Use #20 for up to 200 feet total, #18 for up to 300 feet total.

noid pull in at the rotator and the light on the local-control unit should illuminate.

6. Move the BRAKE switch to Set. The brake should set and the light should go out.

7. Operate the DIRECTION switch. Nothing should happen.

8. Move the BRAKE switch to Release and operate the DIRECTION switch both CW and CCW. The beam should move accordingly. Be very careful as you approach the travel limits—you no longer can see the meter on the remote-control unit. "Jog" the DIRECTION switch when you think you are getting close to a limit to prevent mechanical damage to the beam, rotator, and/or tower.

9. When you are through with the local-control unit, reset the switches to the positions given in step 1, above.

Conclusion

While this convenience may not be desirable to everyone with the HAM IV system, it sure can save you some steps in that special situation. Most antenna rotators operate in a manner similar to the HAM IV, so that the principles shown here can be applied directly to other systems. Remember to check all your connections carefully before energizing for the first time, and be particularly prudent with your ground connections. Grounding systems are for life and equipment protection. Don't cheat! ■

Put Together the Shawnee Logic Probe

It's better than a tomahawk when you're on the warpath against glitches.

Well, here it is. Another logic-probe project. It's not the simplest, most exotic, or highest-frequency probe you've seen, but it works for me.

This probe indicates a high or low at 70% and 30% of V+ (a CMOS specification, but close enough to TTL switching levels to keep you out of trouble). The circuit in Fig. 1 is very straightforward. One section of the voltage comparator (LM393) senses V in over 70% of supply and the second section senses V in under 30%. These two sections direct-drive the appropriate LEDs. You need to be careful of LED current as the LM393 is rated at only 6-mA sink min/16-mA typical. I've had no trouble with the values shown with supplies of 5-12 V dc. The pulse detector is a CMOS one-shot (MC14538) triggered on the rising edge of the LM393 outputs through 1N4148 diodes. With the RC values shown, it has reliably triggered at greater than 30 kHz on both sine and square waves.

Construction should pose no problem. I've built two sizes of probes so far, one in a Continental Specialist logic-probe case and one in a cigar tube. The resistors are all 5%, ¼ Watt except as noted on the schematic. If you're eyeing a cigar tube, you probably will want to find some miniature capacitors. You may want to add a small electrolytic capacitor across the supply leads (1-2 uF), although I've built it both ways with no apparent operating problems. You may substitute a 2N2222 or similar NPN transistor for the MPSA13.

Operation is very simple. You just clip the supply leads to the circuit under test and probe away. The probe's input impedance is greater than 1 megohm, so you shouldn't load down most circuits. If a test point is between 30% and 70% supply, you will get no LED indication. Any logic changes should give you a pulse indication.

Some things you may want to do to your probe are:

1) Give it a pulse memory; tying the Q output to the set input, a resistive pull-up on the reset input, and SPST switch to GRD for reset should work.

2) If you're really worried about overvoltage, you can put a 15-18-volt zener across the supply line.

3) If you need to know the polarity of the detected edge, you can wire in the second half of the 4538, eliminate the diodes, and connect the two inputs to the LM393 outputs, adding a second resistor/transistor/LED.

I hope you find this as useful as I have and get it working the first time around. ■

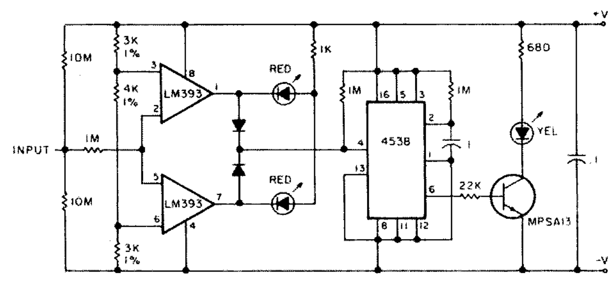

Fig. 1. Schematic. Resistors in Ohms, capacitors in uF. Diodes—1N4148, 1N4154, etc.

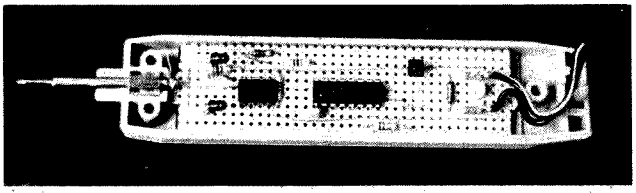

The logic probe.

Parts List

Qty	Item	Cost
2	1N4148 (1N914, 1N4148, etc.)	$.20
2	T1 LED (red)	2.00
1	T1 LED (yellow)	1.00
1	LM393 dual comparator	1.50
1	MC14538 dual one-shot	1.20
1	MPSA13 NPN transistor	.60
2	0.1 uF capacitor	.75
1	1.0 to 10.0 uF electrolytic (alum./tant.)(opt.)	.50
2	3k 1% resistor (hand-picked 5%)	.50
1	4k 1% resistor (hand-picked 5%)	.25
3	1 megohm 5% resistor	.30
2	10 megohm 5% resistor	.20
1	1k 5% resistor	.10
1	680 5%	.10
	Misc. hardware, PC board, case, etc.	10.00
		$19.20

Notes: (1) Resistors 1/4 W (1% may be 1/8 W). (2) MC14538 may be replaced by MC14528. It is pin-for-pin compatible but the RC values will be different (see 14528 data sheet). (3) T1 3/4 LEDs may be substituted if they meet the current tolerances of the LM393. (4) LM393 may be replaced by a quad comparator (LM139/239/339, LM2909, LM3302).

BRAZIL

Carlos Vianna Carneiro PY1CC
Rue Afonso Pena 49, Apt. 701
20270 Rio de Janeiro, RJ, Brazil

BRAZILIAN TIIC-1 TRANSCEIVER

Manufactured by the Intraco Co., this all-solid-state, 100-W-output, Brazilian transceiver is the most up-to-date electronic jewel offered to Brazilian amateur-radio operators.

It works on all bands from 10 to 80 meters, including the new 12-, 17-, and 30-meter bands. It also comes with a 12-V-dc power supply and a 110/120-V-ac unit and has a peak power consumption of 250 W. The TIIC-1 can be used as a base or mobile station.

The frequency range is as follows: 3.5-4.0 MHz; 7.0-7.5 MHz; 10.1-10.15 MHz; 14.0-14.5 MHz; 18.068-18.168 MHz; 21.0-21.5 MHz; 24.89-24.99 MHz; and 28.0-29.7 MHz.

Transmitter carrier suppression is better than 40 dB and unwanted sideband suppression is better than 50 dB, while harmonics and signal attenuation is better than 40 dB. Intermodulation distortion is 25 dB down and frequency stability is ±500 Hz after 30 minutes. The output impedance is 50 Ohms.

The receiver's image rejection is better than 60 dB, and i-f rejection is rated at 50 dB. Selectivity is 2.7 kHz for 6 dB and 5.6 kHz for 60 dB. Audio output power is 3 W with less than 10 percent distortion.

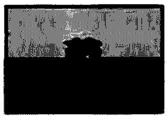
The TIIC-1 is a very nice and distinct rig—a sure bet for love at first sight. Its dimensions are 32 cm × 11 cm × 34 cm deep, and it weighs 8 kg. If it is used mobile, the rig has only a 16-A peak transmitting current.

This rig is almost 100 percent Brazilian—only 5 percent of it is imported—and it is being exported to Colombia and Chile, and possibly to Argentina, Peru, and Ecuador. It costs only $590 US for both the power supply and the transceiver.

Intraco is also introducing an external vfo and wattmeter. These products join the lineup of Brazilian ham gear which includes the RT-1 antenna rotor with a speed of 8 degrees per second.

Considering the Brazilian government's goal of 100,000 amateur-radio operators in the near future, the TIIC-1 and Intraco will be a big help to this program. The 100-W output matches the limits for beginning hams and many older hams will be interested in it as well.

For more information, contact Mr. Jean Weiner, Trade Director, Telecomunicacoes Intraco Ind. Com. Ltda., rua Costa Aguiar 1279, 04204, Sao Paulo, SP, Brazil.



ECUADOR

B. Patricio Recalde S. HC2PP
PO Box 511
Guayaquil, Ecuador

The Guayaquil Radio Club is the oldest club in Ecuador. It was founded on May 9, 1923, by Ignacio Wolf, who was also its first president.

Our anniversary meeting was held last May, with a party and a nice session, the same day as the founding of the club. In this session, diplomas were given to members who have been radio amateurs for more than 30 years. The club also received congratulations in special speeches by civil-defense officials, government officials, and Boy Scout leaders, praising our assistance in emergencies (of which we have had too many).

With this short article, we begin a series that will let you know all of the emergencies that we are handling every month or so. But first I will talk about our meeting place.

It is a beautiful building, three stories tall. The first floor is for administration purposes and in here we have an office with two-meter equipment and a secretary. The office of the club president is also on this floor.

The second floor is where the general assembly hall is located. Although we have many members, this place is large enough to accommodate all of the people who come to our annual meetings.

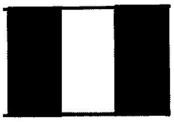
The third floor is where the action is. We have a radio shack with more than ten pieces of equipment so we can transmit on different bands at the same time.

There is a room for storage, temperature and humidity controlled, in which we keep all of the radio equipment and accessories that we need. We have 25 TR-2500s, 7 HF rigs, 6 TR-7850s, antennas for the different bands, batteries, scanners, power supplies, etc.

On this floor is also the room where the weekly meetings of the members of the Directory are held.

We have three towers. Two of them have nothing but Telrex monobanders for each HF band. The other tower is the tallest (105 feet high) and supports all of the VHF antennas. In the two-meter band we have the capability of transmitting in simplex, without the help of repeaters, for 200 kilometers. This range varies somewhat with the weather and other factors.

Since we are members of the IARU, we will give information related to it, too. There was a meeting recently in Cali-Colombia, where HC2NW represented the 2730 members in our country. If you plan to come to Ecuador, please let us know so that we can make your stay more comfortable through the hospitality of amateur radio.



FRANCE

Claude Guae F1DGY
11 Rue Emile Labiche
28100 Dreux, France

Each year since 1976, club station F1KJC has organized a hamfest at the end of June. This club belongs to a French color CRT factory (Philips-RTC) located in Dreux.

Dreux is a small town of 40,000 inhabitants located 50 miles southwest of Paris, on the borderline of Normandie and Ile de-France. There are few hams in this town, so the majority of the participants come from the surrounding countryside.

As far as weather is concerned, June is generally sunny—important for a picnic.

Mobile operators are guided to the picnic area on 145.525 MHz. The access is not very easy...a simple beaten path leads to the site, and you have to beware of tree limbs which will snag your antenna.

At noon, it is time to light the barbecues for the "merguez" (spiced sausage) and it is also time for a drink, of course. The next hour is spent chatting with one another. After the last merguez and the last drink, the camping equipment is put under the trees. Then coffee is served, to fortify those who would rather nap than try to find the fox.

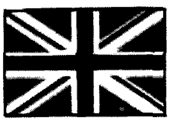
This year, two beacons (200 mW, 144.700 MHz) were hidden in the woods 2-3 miles apart. The winner of this eighth fox hunt was Daniel F6AJJ and his buddy William F6DLA. Daniel has won the hunt before, in 1979 and 1982, so he got to keep the club cup for 1983.

Thanks to all of the participants at this hamfest for their very nice spirit. Now we have to begin thinking of the next one!

5TH PHILIPS QSO PARTY

French Philips employees and employees of its affiliate companies have organized this year's QSO Party. Each ham who belongs to this group worldwide is welcome to participate. Rules can be obtained from the country coordinator or from Eric Ludwig F9LT, 9 Rue de la Broaderie, 78340 Clayes Sous Bois, France.

The HF CW contest will be held Nov. 5-6, and the HF SSB portion will be on Nov. 12-13. HF RTTY and SSTV entrants will be competing Nov. 5-13, and the VHF/UHF contest was held Sept. 17-18.



GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Widnes WA8 9RP
Cheshire, England

By the time you read this, you will probably have heard some new prefixes from the UK. On the HF bands, G0 calls will be active, whilst G1 calls will be on VHF (and may be heard in the US via satellite, of course).

It occurs to me, therefore, that an explanation of the UK callsign allocation system would be of help. Even without considering special-event callsigns or experimental licenses, the UK contributes no less than 58 prefixes to the WPX program!

UK callsigns are divided into three main parts: the country designator, the operator identifier, and the optional suffix. The most important of these items is the operator identifier and so I will deal with this first. It consists of a figure and two or three letters. In my case, the operator identifier is 4EJA and this, like all others, is unique (but there could be a 3EJA or an 8EJA, etc.).

The figure indicates the class of license held, this being either class A or class B. A class-A licensee may use all bands and all modes and has passed a written test and a 12-wpm code test. A class-B licensee may use only the VHF bands (144 MHz and above—note the exclusion of 50 MHz and the Region One allocation at 70 MHz) and any mode except CW. A class-B license is obtained by passing only the written test.

The prefix number (in conjunction with the number of letters in some cases) indicates the license class:

Number	Letters	Class
0	all	A
1	all	B
2	all	A
3	all	A
4	all	A
5	all	reciprocal
6	two	A
6	three	B
8	two	A
8	three	B

(Note that 7 and 9 are reserved for a few special experimental licenses.)

Preceding the figure is the country identifier. In my case, my station is licensed in England, so I use G. However, if I drive down to the Principality of Wales (which I can do in about 40 minutes), I must change the prefix to GW.

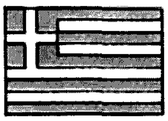
The country prefix therefore indicates the location from which the station is operating rather than in which it is licensed; if I travel to Scotland, I become GM4EJA. The full range of UK country prefixes is: G—England, GM—Scotland, GI—N. Ireland, GW—Wales, GD—Isle of Man, GJ—Jersey, and GU—Guernsey.

As well as a possible change in country prefix, the traveling ham will almost certainly have to use a suffix. Operating from my car in Wales, which I do occasionally with an FT-290 and a 30-Watt linear, I sign GW4EJA/M—the suffix indicating mobile.

If I walk into the mountains with my IC-2E handie-talkie (admittedly not very likely), I sign GW4EJA/P—this time the suffix indicating portable.

If I set up a semi-permanent (i.e., mains-powered) station in my trailer near Appleby in the English Lake District, I sign G4EJA/A—this indicating an alternative address.

Finally, I must mention GB prefixes which indicate special-event stations (usually at fairs or fetes, etc.) and which may be operating from any country in the Kingdom, as may beacons and repeaters which also use the GB prefix.



GREECE

Manos Darkadakis SV1IW
Box 3751
Athens, Greece

As in every country, Greek radio ama-

teurs have their preferences about which bands they enjoy working. There are HFers and VHFers, and others who prefer to spread their activities over all bands if possible, or in all modes. Of course, I left the most important thing until the end, and that is our wallets. You may want to do a lot, but...

Anyway, back in my first days of hamming, HF was what everyone was using. Many people had home-brew rigs, some had Heathkit or Yaesu gear, and the elite used Collins equipment.

Outside of the HF bands, a few people with Twoers were exploring the challenge and mystery of VHF. But the revolution in the electronics industry did not miss Greece. In my country, this started in 1978, but it was not only the competition between manufacturers—it also stemmed from competition among hams.

Those days, and for quite some time afterward, to be a respectable ham in Greece (and other places, too, I believe), you had to have a couple of HF rigs, two or three VHF radios (base, mobile, and portable), one or two UHF transceivers, and, of course, a RTTY or SSTV terminal—just to name a few.

The antenna was the last thing under consideration. Even today, can you imagine a $2000 FT-ONE on a CB antenna modified for 10 meters? Well, I can.

It is really amazing to see what has happened in Greece in the last two or three years. We can buy Yaesu and Icom gear even before it is advertised in England or the US. Therefore, most of the HF rigs in Greece today are Icom (720s, 730s, and 740s) and Yaesu (FT-ONEs, 707s, 102s, and 980s). There is also Drake and Kenwood gear, and even some fancy rigs like the Collins KW-380. Palomar's state-of-the-art rig was available some years ago.

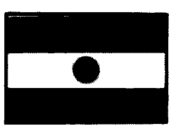
Nowadays, there are a lot of SV hams active on HF bands, but only a few of them are active DXers. About 80 percent of all hams in Greece have 2-meter rigs and 60 percent of those have an all-mode transceiver. 20 percent are active on UHF as well, again with all-mode rigs. Finally, five or six hams are active on the SHF bands.

Of course, SSB and FM are the most popular modes on most bands, with CW a distant third. In the specialty modes, about fifteen people are working RTTY and there is a handful of slow- and fast-scan TV and satellite operators.

In closing the column this month, I will mention the existing repeaters in Greece, with more information to come soon.

On VHF, we have R1 situated in Athens, R3 in Heraklion on the island of Crete, R5 in Volos in the central part of Greece, R6 in Thessalonika, and finally R8 on the island of Lefkas in the Ionian Sea. There is also a UHF repeater, RU1 in Athens and a UHF transponder linking the R6 VHF repeater with RU6 frequencies on UHF.

All repeater frequencies are established according to the IARU Region 1 band plan, with the input −600 kHz on VHF and −1.6 MHz on UHF. None of them has tone access.



INDIA

James Kalassery VU2ARL
PO Box 1446
36/677 Monastery Road
Cochin 682011
India

1983 is a remarkably good year for amateur radio in India. Thanks to our government and the Federation of Amateur Radio Societies of India (FARSI), we now have a few WARC bands and more privileges—more power for the Advanced class, more modes for Grade I, and more bands for the Grade II licensees.

The Wireless Planning and Coordination (WPC) Wing of the Ministry of Communications, which regulates amateur radio in India, has recently released two WARC bands—18 MHz and 24 MHz—for use by radio amateurs on a non-protective, non-interference basis. With this gesture, India is now placed among the few countries which have permitted their amateurs to operate on these new bands. After our government allowed the importation of amateur-radio equipment and accessories under the Open General License of Import Policy, many amateurs bought equipment which enabled them to start operation as soon as the new bands were released. We hope these new bands will open up new vistas of activities in the fields of operation and research for improved peripherals.

Now, Advanced-class amateurs can run up to 400 Watts (as opposed to 150 Watts previously) input on selected portions of the HF bands. Grade-I amateurs can work on all modes, some of which (SSTV, RTTY, etc.) were previously reserved for the Advanced class. Grade-II amateurs, who were allowed to operate only CW on 80 and 40 meters and phone on 2 meters, now can operate CW on all HF bands and phone on 10 and 2 meters. Their power also has been raised from 25 Watts to 50 Watts dc input.

Our government is now keen on promoting this unique hobby. While previously we had to obtain express permission from WPC to move stations even for demonstrations, etc., now we just have to intimate them in advance. Testing Morse code for the licensing examination also has been made simpler, though the speed standards are the same as before. The requirement of copying continously for five minutes with a maximum of five mistakes has been relaxed to copying correctly for any one minute (out of the 5 minutes) continuously.

These relaxations, announced during this World Communications Year, have come as a result of a meeting the representatives of our radio amateurs had with the Wireless Advisor last December. With more changes expected to be announced shortly, amateur radio certainly has a bright future in India.

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office
85530 Israel

As I write these lines, the reverberations from the 35th annual General Assembly of the Israel Amateur Radio Club are still echoing in my mind. So, for this month's column, I would like to give you an account of the proceedings.

The meeting was opened by the chairman, Yankele 4X4AH, telling us that he believes that hams are a group of individuals wishing to enjoy their hobby with a minimum of interference from neighbors and authorities. With this in mind, he made a plea for unity, urging us to remember above all the purpose of our organization.

Naftaly Balaban 4Z4RM, the outgoing president, surveyed the past year's goals and achievements. He then went on to the presentation of awards and trophies for achievements in national competitions and to outstanding amateurs and clubs.

Alon Tavor 4Z4ZB was named amateur of the year in recognition of his devoted work at the Alyn Hospital for Handicapped Children in Jerusalem. He established there club station 4Z4SW and conducts classes and on-the-air sessions for the children who are largely confined to wheelchairs. Alon invites amateurs visiting Jerusalem to drop in on the club.

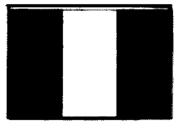
Ron Roden G4GKO was presented with honorary life membership in the IARC in appreciation of his representing us over the past years at meetings of the IARU. Ron, deeply moved, said it was his privilege to represent Israel, and he would continue to do so as long as needed. I must point out that the IARC, being a relatively small organization, has never been able to support sending a delegate to international conferences, and Ron, whose work takes him around the world, is happy to represent us. Ron spoke of the aims of the IARU in these days of crowded bands and said that in next year's meeting in Sicily, the organization will deal with band planning and try to set aside frequencies to be free from competitions.

Speaking for the Ministry of Communications, Israel Biber 4X4OR spoke of the problem of self-discipline in the amateur ranks. He said that the Ministry intervenes when "the waters run over" (translation mine) and that it was forced to take action against a few illegal operations this past year. These actions are most brutal, as the police make little distinction between illegally holding arms or transmitting equipment. Mr. Biber pointed out that there are currently 80,000 radio transmitters licensed in Israel, largely on VHF, averaging 200 stations per channel, all casting hungry looks at our wide spectrum allocations. Thusly ha exhorted us to keep our frequencies clean and preserve our rights.

After these presentations, a free discussion was held that, due to the late hour, was limited by time. A past treasurer, Tuvia 4X4GT hauled up to the podium an empty satchel. This bag, he said, could contain a hundred thousand shekels (roughly $2,000) for the club treasury, had a raffle of equipment been held, as was done in previous years. Ben 4Z4JS suggested that next year a raffle of only a few good pieces of equipment be held, instead of the time-consuming draw of scores of pieces of junk.

A slate of candidates for the new club executive was proposed by Aharon 4X4AT, and with no opposing candidates proposed, the list was unanimously accepted. The new officers are as follows: 4X4s AT, JT, GT, and NOE; 4Z4s NU, RZ, UR, US, and NUT; 4X6s DW, LM, and NFK. This is, to my mind, an excellent group of active and involved amateurs who have all pledged to give the most of themselves for the good of our national organization. This strongly contrasts the situation at last year's general meeting when arms had to be twisted to get people to agree to be nominated. This was reflected in much of the activity of last year's executive, and it looks like this year people were shaken out of their apathy and have come forward to give us a stronger club.

At 11:30 pm, the management began flashing the lights of the auditorium, signaling us that our time was up. For the next hour and a half, the 2-meter repeaters and simplex channels were buzzing as a few hundred hams made their way back from Jerusalem to Tel Aviv on the Mediterranean coast, to Beersheva and the Negev in the south, and to Haifa and Galilee in the north. Once again, the yearly rites of the IARC General Assembly had come to an end.



ITALY

Dr. Giancarlo Martelli I0XXR
18, Vie Bevignani
00162 Rome, Italy

VATICAN CITY

For many hams, the HV prefix is still an elusive and rare one. Here is some late information about the stations active from Vatican City.

HV3SJ

This station is located in the Jesuit Headquarters Building, just a quarter of a mile from St. Peter's Square. The building is outside the Vatican State border, but being property of the Vatican itself, is considered extraterritorial by the Italian state, by virtue of the agreement between Italy and the Vatican. This station is active almost exclusively during the weekends and is operated by Pino D'Aurelio I0OUD, who prefers SSB. Father Larry, a CW enthusiast, also uses the station.

The HV3SJ facilities are a Collins S-Line and a threeband, twoelement, cubical-quad antenna. No low-frequency antennas are sat up there. The QSL traffic is managed by I0OUD at his home address: Giuseppe D'Aurelio, Via Fogazzaro 87, 00137 Roma, Italy.

HV1CN

The station is housed in a small room in the same building as the studios of Radio Vaticana, together with the VHF/FM broadcasting station.

The medium-wave and shortwave transmitters of Radio Vaticana are located at S. Maria Galeria, a locality 25 km from Rome, where the huge display of towers and curtains is the dream of any ham who passes by. An auxiliary 25-kW shortwave transmitter is located a few hundred feet from the HV1CN shack and radiates its power through a log-periodic rotary antenna.

The combination of HF and VHF waves fills the air at HV1CN, so heavy IMD and overloading occurs very often in the receivers of the ham station.

The equipment is a slightly-outdated Hallicrafters line, but its tube-equipped front end beautifully resists the attacks from the nearby broadcasting transmitters. The antenna is a TH8 beam for 10, 15, and 20 meters. No LF antennas are here, either.

The chief operator of HV1CN is Domenico Petti, the chief engineer of the broadcasting station; very often, he welcomes guest operators.

The station is not very active due to the fact that Domenico is an employee of the Radio Vaticana and lives in Rome, outside the Vatican borders, so he is very busy with his job when he is in the building.

QSL cards should be sent to HV1CN, c/o Vatican Post Office, Citta del Vaticano, Rome, Italy. Be careful not to send QSL cards for HV1CN through the bureau, because the only bureau in Italy is the ARI bureau, which has no connections with the Vatican.

HV2VO

This station is located in the Vatican Observatory of Castel Gandolfo. The building is a big, ancient castle which houses the summer residence of the Pope

and holds extraterritorial status. Castel Gandolfo is a small city about 20 miles from Rome.

The HV2VO station is operated by Father Edmund Benedetti, only on SSB. The antenna farm has a three-element beam for 10, 15, and 20 meters and inverted-V antennas for 40 and 80 meters. Since the Vatican Observatory building is on top of a hill, the location seems to be very good for radiating signals, and the HV2VO signal is very consistent around the world.

This station is fairly active when Father Edmund is not traveling abroad and offers the only chance to work the HV prefix on the 40- and 80-meter bands.

The QSL manager of this station is Giancarlo Gottnich I0GPY, Via Vigne Morena, 90-00040 Roma Ciampino, Italy.

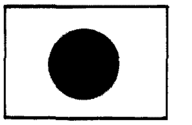
THE ARI DOCTORS AND RADIO AMATEURS GROUP

This group of radio-amateur hams was founded five years ago, and since then it has grown and achieved much acclaim for its emergency and welfare activities related to amateur radio. The group is working inside the ARI (Associazione Radioamatori Italiani) and is connected with the ARI CER (Corpo Emergenza Radioamatori).

Every year, the group's members meet in Foligno, a fascinating town located in Umbria, central Italy. There they discuss their activities with regard to radio telemetry and the transmission of medical parameters via amateur radio—things like electrocardiograms, radiographs, etc.

Some members of the group have recently been to China, where they gave demonstrations of the experimental work done through amateur radio. The Chinese Sports Ministry hosted these MD hams and invited them for another trip to China—this time with their ham equipment.

The group holds its net daily on 40 and 80 meters, so medical aid over the air is available in every emergency.



JAPAN

Shibuya-Ku
Tokyo 151, Japan

ILLEGAL OPERATORS IN JAPAN? AMERICANS NOT ALLOWED TO QSO WITH AMERICANS?

Judging from the title of this month's column, one would get the impression that things are a little screwed up in Japan as far as ham radio is concerned. They are! Let's review the situation in brief, as those of you who may have tuned in late, that is, those of you who have not read the previous months' columns, may be a little confused. Shame on you.

As of this writing, Japan has no reciprocal licensing agreement with any country. A law was passed by the Japanese government in May, 1981, that ostensibly permits the signing of reciprocal agreements with other countries. The Japanese have privately stated that their goal is to sign the first agreement with America. The other countries can wait. The Japanese government made their proposal to the US government, but it was wisely rejected by the US because it contained certain objectionable provisions, such as station inspection, the necessity of permission from the owner of the premises where the station would be located, and a rip-off license fee.

While this is being written, the two governments are squabbling over these and other points. It is possible (but unlikely) that by the time you read this, the problems will have been resolved and that the first reciprocal agreement with Japan will have been signed. I wouldn't bet very much money on it, though.

However, American and German operators can operate in Japan by using a club station callsign and have been doing so since 1970. This was brought about by former US Ambassador to Japan, Armin H. Meyer W3ACE, who persuaded the Japanese authorities to make a minor change in the law. Under this system, most foreign operators run only 10 Watts, as higher power would require an inspection, requiring a 6-month or longer wait, plus an inspection fee. Note that the Japanese government does not issue callsigns to non-Japanese amateurs. Operators' permits only are given to foreigners who hold a valid FCC or German amateur license. The callsign must be in the form of a Japanese club callsign which is "lent" to the foreign operator.

Finnish and Irish hams also have been given this same privilege during the past two years.

And that's how things stand at present: Only amateurs from America, Germany, Finland, and Ireland can operate a club station in Japan.

ANOTHER WAY TO GET ON THE AIR IN JAPAN...

There is still one other way to get on the air in Japan. If you can read, write, and understand Japanese, you have the unique opportunity to take the Japanese-language amateur-radio exam. If you pass it, you will receive a lifetime Japanese operator's permit. But note that this still does not get you a callsign. Remember that under present regulations, callsigns are given only to Japanese citizens. So you still have to find a club station to operate. Several hams have done it. We believe that the first person to take and pass the Japanese exam was Norman Smith G3HFO, who was a member of the British Embassy. That was in 1970. Norman enjoyed operating a Japanese club station for several years. In more recent times, Keith Wilkinson ZL2BJR also obtained his operator's permit this way. It should be noted here that the JARL runs training courses designed to ensure that you pass the test. The test itself is a multiple-choice type. So, as you can see, although it is not impossible to do, and even though Japanese is not a difficult language to learn to speak, learning to read and write it takes some real effort.

AND STILL ANOTHER WAY...

There is one more way to get on the air in Japan. This is not necessarily the recommended way, and as a matter of fact, the only person to try was only marginally successful. Here is the way it works: It is said that from a legal standpoint, an embassy or consulate located in a foreign country is not really on foreign soil at all. In other words, the argument goes, the British Embassy that overlooks the Imperial Palace grounds (there's where the Emperor and Empress of Japan live) in central Tokyo is really British territory. Looks can be deceiving. Mr. John Donald G4JFM, who lives and works in the British Embassy here in...*uh*...Tokyo (or I should say in the British Embassy on British soil somehow transplanted to the center of Tokyo), realized this fact and went to the British Ambassador to get his opinion. The Ambassador said, in effect, "John, you're on British soil! Go on the air. I'll back you up." So, in February of this year, John went on the air, signing G4JFM/JA. John had a lot of contacts with stations all over the world, including QSOs with friends back in his home country.

He also received a lot of on-the-air threats from Japanese hams who asked a lot of questions. John answered them all honestly. The threats continued, ranging from the classical but unoriginal type of "I'm going to report you to the Ministry of Posts" to the more original type of "Get off the air, white pig!" This from our nice, gentle Japanese ham neighbors who can go to the United States, take the test, and obtain their own genuine US ham callsign. In fact, many Japanese hams are doing this as part of their collection, much the same as one goes overseas and brings back an ashtray or other souvenir (mostly made in Japan). Furthermore, Japanese hams can now go to the UK and obtain a permit to operate, even though no reciprocal agreement exists between Japan and that country. In fact, John worked a Japanese amateur operating from Britain. But some people are not persuaded by those arguments.

The slurs, threats, and especially the jamming got so bad that John finally gave up—temporarily, at least. Now you would think that in a democracy, as Japan is purported to be, the citizenry would understand that it is the exclusive duty of the government to decide if a law is broken and take whatever action is required. For a citizen to take it upon himself to interpret the law and censor another person without due process of law reminds one of the lynch mobs that once pervaded the western part of the US many years ago.

John has a good view at least. He is able to sit at his operating table and gaze from the shack-room window upon the beautiful Imperial Palace grounds on the opposite side of the street beyond the moat (no crocodiles or alligators in the moat) while he sips his tea. English tea.

NO OTHER WAY...

Some ham-radio operators who come to Japan do not have these options open to them. For instance, Rossella Strom I1RYS is not American, German, Irish, or Finnish. She is Italian and therefore she can't go on the air under the club-station system. She is not fluent in Japanese either, not having been in Japan very long, so she couldn't very well take the Japanese exam. And she is neither working nor living in the embassy of a foreign government. She is an attorney, although her reason for coming to Japan was to accompany her businessman husband. So for her, there is no way to get on the air in Japan. She can't even speak over the microphone of a Japanese friend's station, as that is prohibited in Japan. Only a holder of a valid Japanese operator's permit can do that. She will have to wait for a reciprocal agreement. Incidentally, she wasn't allowed to practice law in Japan either. That's prohibited, too! Last week she solved her problems in one fell swoop. She and her husband moved back to Italy.

AMERICANS NOT ALLOWED TO SPEAK TO OTHER AMERICANS!

As an American living overseas, it's sometimes nice to have a "local" QSO with another American living in Japan. Having QSOs with Japanese and other hams is always fun, but nothing beats having a QSO with a fellow American. No harm there, right? Well, it "ain't necessarily so" says the Japanese government.

Some of you may remember that there was once a war called World War II that ended in Japan's defeat in 1945. Allied occupation forces came into the country at that time, and the hams among the occupation forces were given permission to operate ham radio from Japan. When the peace treaty was signed in 1952, the US troops were no longer "occupation forces" but instead came under the agreement called the Status of Forces Agreement, or SOFA. Under SOFA, the military was given certain rights to establish communications as they saw fit. Under this authority, the US obtained a block of callsigns from the FCC to use for US hams stationed in Japan under SOFA. The FCC does not license these American military hams for Japanese operation, as they already possess FCC licenses. The licensing authority for operating in Japan is the American military command in Japan. The callsign prefix is KA, with various numbers following that which identify the region within Japan, followed by two letters.

The situation was going quite well until September, 1959, when, it is reported, a Japanese ham who apparently disliked American GI hams operating in Japan (in spite of the fact that we gave them their country back after fighting a vicious war) challenged the Ministry of Posts to define the legal status of these hams. Note that they were operating on military bases only. The military authorities prohibit KA operation off the base, thereby recognizing the sovereignty of the Japanese government to control ham-radio operation on pure Japanese soil. It's interesting that the US government considered and still considers US bases not to be on Japanese soil, for the most part. Sounds familiar, doesn't it? Anyway, the ministry buckled under and ordered, through the JARL, Japanese hams not to have QSOs with US military stations or face license revocation. The US military also ordered its KA stations not to have QSOs with Japanese hams so as not to aggravate the situation.

Now we move up to 1971, when a lot of American civilian types living in Japan, assigned to Japan on business or teaching positions, began to obtain Japanese club-station callsigns. This often resulted in some interesting exchanges. Sergeant John Smith KA2SS is located on a US Air Force base 30 miles west of Tokyo and operates from his on-base quarters. Roy Waite JA1YSH is a businessman and operates from his condominium in Tokyo:

KA2SS: "CQ, CQ, CQ. This is KA2SS calling CQ and standing by."

JA1YSH: "KA2SS. Calling KA2SS. This is JA1YSH calling KA2SS and standing by."

KA2SS: "Sorry, old man; I can't QSO with you. Are you an American using a Japanese callsign? Over."

JA1YSH: "Yes, I am. I am operating a Japanese club station. By your call I thought you were on the west coast of the US. Too bad we can't QSO. Do you get to Tokyo sometimes? Over."

KA2SS: "Sure do. Let me have your phone number and I'll contact you next time I come to town. By the way, you're 5 and 9 out here. The handle is John. Over."

JA1YSH: "OK, John. The handle is Roy. You're 5 and 9, too. Yes, I'll give you my telephone number. Too bad we can't QSO..."

Sounds a little silly, doesn't it? If you think that's funny, you should hear the SEANET (South East Asia Net) when a Japanese takes over as the net controller. During the roll call, whenever he comes to the KA stations, he has to turn over the controller job to a non-Japanese station such as a Hong Kong station, to call in the KA stations. When that's finished, the Japanese net controller resumes the roll

call for the rest of the stations. As you can see, the rest of the world recognizes the US military ham stations in Japan as legitimate hams, while Japan does not.

For a time, there were some US military civilian workers who were operating on both sides of the fence. That is, they used a KA station while on the base, and at night at home, they used a Japanese club station. This went on for a few years, until the Ministry of Posts realized what was happening. The Ministry of Posts has committed a number of mistakes and contradicted itself several times, such as allowing one thing one time and disallowing it later. The operating word here is "inept."

I said earlier in this article that ham radio is a little screwed up in Japan. After thinking it over, I'd like to retract that comment. It's more than a little.

POLE PIG REVISITED

So you have always wondered what we do in West Africa when we take diagonal cutters in hand and go outside to do a little antenna work, right? *Well, it is much* the same as you might imagine they do it in Florida, i.e., cut, sweat, trim, and measure the swr, over and over again. However, we do it more often than you do it.

Not that we aren't so good at cutting, sweating, trimming, and measuring the swr, but there are a few other factors that you must consider. You can't just pick up the telephone and have a nice antenna at your doorstep in less than a week, even if you have the money. So if you want a beam, you end up with a quad. Quads are a dream here, supposedly high gain with short booms on low towers, lots of free bamboo, no icing, and low wind. But the cutting, sweating, trimming, and measuring of the swr is a nightmare on a home-brew quad. And the humidity is so high that the bamboo rots in a couple of years, requiring restringing of the spider's web.

Also, a large portion of the amateur community is expatriate and lives here for only a few years. So, many of us are just setting up ham stations from scratch. And as the hams turn over, there is always someone else starting over again. Consequently, we make a lot of dipoles.

So here you are, out cutting copper wire on a hot weekend. The nice roll of #14 enamel-coated copper wire that you brought from the States that cost you a fortune is rapidly dwindling, and it makes you nervous to roll off another 20 feet. Cut, sweat, trim, and measure the swr. You would sure like to lend some of your friends some good wire when they make their own antennas, but soon you won't have enough for yourself. Your friends go to the electrical supply store in the capital city to buy their insulated rolls of copper wire, and you thank God during your evening prayers that you didn't have to stoop to paying for copper with gold and then have to strip the insulation off. Cut, sweat, trim, and measure the swr. The new antenna begins to take its final form. You pat yourself on the back and say to yourself that, if nothing else, you really know how to make an antenna. The antenna is finished and works fine.

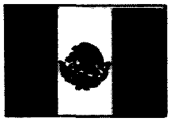
Later in the month, you help a new African ham make his own antenna using your design. Cut, sweat, trim, and measure the swr all over again. After a little snafu, it works perfectly. But that wire was just too expensive and you wish you had enough to just give the poor fellow so the struggling new ham didn't have to buy it.

Then you have a vision, you know, one of those sky-opening experiences where a voice calls out and gong goes off, something like when you have just worked a new country. You are walking past an old, dead, 10-kVA power-line transformer sitting on the ground. You know, the same one you have been walking by for the past three years. And you remember like a bolt of lightning the article you read a year ago about how there are nice high-tension transformers inside those big, ugly, rusting, grey cans. You also remember that even spoiled transformers have lots of wire in them, and that big spoiled transformers have big wires in them, and that the wires in transformers are enameled copper wires.

Then you plan for 2 or 3 weeks how you are going to get your hands on the transformer, and you make the necessary arrangements with the organization that you work with to take the old transformer which has been broken since as far back as anyone who presently works there can remember. They are, in fact, happy to get rid of it. Little do they know of the treasure inside. Why, you would steal for antenna wire in an emergency, and they are happy to get rid of it. The only catch is that they want the transformer coil that is inside, and that is just the part you don't want.

When you finally get the transformer out, it is so big you can hardly lift it off the ground. When you were a kid, you used to take a few small transformers apart and marvel at all the wire inside, but it was nothing like this. Lord knows that there must be hundreds of feet of wire in that thing. You get it home and start unwinding it. The wire on the high-tension primary is #14, exactly what you brought from the states, only 10 times as much, and free. There is so much wire that you will have enough for retirement when you can make antennas every day. And the low-tension secondary wire is the biggest single-strand wire you have ever seen in your life. In fact, it looks like a long copper bar 1/4 inch wide and 1/8 inch thick. There isn't so much of that, but you can already think of hundreds of uses for it.

And you suddenly realize that there are thousands of old broken transformers all over this country, and 10 kVA is the smallest that you can get. And you realize there will never be a wire problem again. And you sleep unusually well that night. Now if there was only an easy way to get insulators . . .



MEXICO

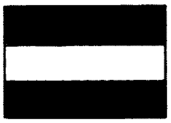
Mark K. Toutjian XE1MKT
Apartado Postal 42-048
06470 Mexico, D.F.

Little has been written with regard to "Mexico airwaves" and ham activity here down south of the border over the years. Nevertheless, much has been going on and most of it is known by our fellow colleagues within the country. We are constantly having DXpeditions, contests, and radio-club get-togethers, and ham-radio operators from all around the globe can qualify for one of the many diplomas (awards) available from the Liga Mexicana de Radio Experimentadores (what we might call the "Mexican Radio Relay League" or the "Mexican Radio Experimenter's League") which has its base in Mexico City and controls the radio clubs all around the country.

Many of the different radio clubs from different parts of Mexico also offer attractive diplomas to fellow hams around the world. Now that Mexico joins "73 International" with its own monthly column, I hope to cover practical material and up-to-date information for all of you *73* readers so you can qualify for and obtain diplomas from our Mexican Radio Experimenter's League, make your OSOs with our DXpeditioners, and enjoy current information that is also shared with our local hams.

At the time of this writing, a couple of DXpeditions happen to be going on here! One is going on at what we call "El Mar de Cortes" (The Sea of Cortes) near Baja, California, and the other at "La Isla de los Alacranes" (Scorpion Island) near the southern tip of the Yucatan Peninsula. There are also rumors of a few hams from Mexico who will be on a DXpedition by boat from Mexico via Africa. We will keep you informed of their schedules and frequencies beforehand.

Are you thinking about taking a vacation to Mexico in the near future? Did you realize that there are all kinds of tourist opportunities with Mexico's past devaluations? Perhaps you would like to listen in on two meters and would like to know more about the repeaters available throughout the country, especially in tourist zones. You will be informed about this, too, now that Mexico has joined "73 International." You may also have a few questions about regulations here in Mexico and agreements between Mexico and other countries. This also will be considered. As a correspondent for *73* from Mexico, I would like to invite our Mexican readers to get in touch with me by radio or mail upon hearing of or planning any DXpeditions, contests, radio-club activities, or otherwise. So, *look for* my column next month! Join in with Mexico, as Mexico joins "73 International." *Adios* and *hasta la vista* for now. 73 and DX!



THE NETHERLANDS

Henk Meerman PD0DDV
Zandvoorterweg 33
2111 GR Aerdenhout
The Netherlands

The national Dutch amateur-radio station PA0AA owned and operated by the largest amateur radio society in Holland, VERON, is on the air every Friday on the 80-, 20-, and 2-meter bands on 3.600 kHz, 14.100 kHz, and 144.8 MHz with the following schedule (times in UTC):

1900 News in Dutch (weather forecast, news about contests, etc.)
1915 News in English (weather forecast, news about contests, etc.)
1930 Code course for beginners
2000 Code course for the advanced
2030 RTTY news bulletin
2100 Repetition of the news in Dutch
2115 Repetition of the news in English

At 2130 UTC, PA0AA will be listening for amateurs with questions and will make some OSOs.

CB RADIO IN HOLLAND

Although it has little to do with amateur radio, I want to write something about CB radio in Holland. Every Dutch citizen who has reached the age of fourteen can get a license for CB. In Holland, only factory-made rigs with a special certification mark on the front are allowed. The output must not exceed 2 Watts. Furthermore, only the use of 40 channels and FM modulation with an omnidirectional antenna is permitted. The annual license fee is 35 Dutch florins. It is also possible for foreigners to get a CB license in Holland. For details and information, you can write to the Dutch Post and Telecommunication Administration. The address is: PTT Radiocontrole Dienst, afd.MARC.-machtigingen, Postbus 570, 9700 AN Groningen, The Netherlands.

SPECIAL AWARD

Among the many awards which we have in Holland, there is a very interesting and special one. It is the Airborne Memorial Award. This award is founded in remembrance of the airdrops of September, 1944, at Renkum, Wolfheze, and Oosterbeek previous to the battle of Arnhem (September 17, 1944).

The clear profit of this fund goes to the Airborne Forces Security Fund. The money from this fund in many cases helps the close relatives of flyers to come to Holland (Oosterbeek) and to make a visit to the graves of the men who gave their lives for our freedom during WWII.

Every year on the 17th of September, the hams who live in the region of Renkum and Oosterbeek will come on the airwaves and identify themselves with "CO AMA" (Airborne Memorial Award). For details and information, write: PO Box 80, 6860 AB Oosterbeek, The Netherlands. Please enclose two international reply coupons.

NEW ZEALAND

D. J. (Das) Chapman ZL2VR
459 Kennedy Road
Napier, New Zealand

Greetings from ZL again. Over the next few months, I shall endeavor to cover some of the specialist groups within the structure of New Zealand amateur radio. The first on the list, in honor of its 21st birthday year, is the WARO Club, the Women's Amateur Radio Operators' Club of NZART.

WARO was formed as a result of a suggestion made to a small group of YL operators at the 35th annual conference of NZART at Hamilton in June, 1961. The idea was met with enthusiasm, national nets were begun in July, 1981, and all YL operators were contacted by letter outlining the proposal and advising details of the inaugural meeting at Rotorua on March 10, 1982. Those present at that first meeting were Thelma Souper ZL2JO, Florence Voss ZL1AXP, Judith Holland ZL1AWM, Celia Reed ZL1ALK, Jannette Barker ZL1ANA, Vicki Shaw ZL1OC, and Enid Rosen.

WARO was honored to have among its founding members a few YLs who had been on the air since the early 1930s, notably Thelma Souper, the first secretary/treasurer, and Myrtel Earland ZL4GR, New Zealand's first licensed YL operator, a lady of some renown who is still active after more than 50 years of amateur-radio operating.

The constitution of WARO, "to promote and encourage friendship and interest in

radio amongst women radio operators," has been well fulfilled since the beginning with just a handful of members. Today, there are 92 licensed YLs, 37 overseas YL operators, and 23 associate members. These figures mirror the steady progress which is continuing, as well as WARO gaining worldwide recognition within international amateur-radio circles. The first overseas WARO member was Mildred K9HRH, who joined in 1963. She became a silent key in 1989.

In 1969, the WARO Award was introduced—it features an attractive certificate of "Pania of the Reef" (a female from Maori legends), with additional seals for extra YL contacts after the basic award. The details of the WARO Award appear later in the column.

The WARO also have an annual HF contest which is thoroughly enjoyed by YLs and OMs alike, the winner receiving the "Thelma Souper Memorial Cup," named in honor of Thelma, a founding member and past president of WARO, who bacame a silent key on 16 December 1977.

In 1981, WARO adopted an emblem and included it in a WARO badge which is now proudly worn by all members.

Pen pictures of some of the early WARO members must include the Grand YL of New Zealand amateur radio, Myrtle Earland ZL4GR. Myrtle, of Dunedin, better known to operators around the world as "Myrt," became ZL's first licensed woman amateur-radio operator in 1930 with the callsign OZ3AG. Like so many of the very early licensed operators, Myrt was an expert at CW; during World War II, Myrt and her OM, Fred ZL4AM, were at a QTH about 120 miles from Dunedin at Omakau. There they monitored the HF bands, recording coded enemy messages and sending them by a direct telephone "wire" to Dunedin. As Myrt dryly comments, it was the longest antenna she's ever had, but the landline had to be used because during the war years, amateur-radio operation was suspended and transmitters were sealed by the government to prevent unauthorized transmissions. In later years, Myrt moved to Dunedin, where she has had many contacts, but the most exciting to her was the one with an operator on board the prime recovery ship for the Apollo X astronauts on 28 May 1969.

Myrt has also been involved in emergency operations over the years, the earliest being the 1931 Napier earthquake, when she acted as a relay station for messages. More recently, Myrt was on duty in the Green Island (Dunedin) Civil Defense Headquarters during the Abbotsford landslip emergency.

For her 50 years as an amateur-radio operator, WARO presented Myrtle with a very special WARO Award in 1980, in recognition of the Grand YL of ZL radio.

Thelma Souper ZL2JO (silent key), who was first licensed in March, 1931, as ZL2FR, later ZL1CN and ZL2AO, operated 40 meters when 40 was a CW-only band. After World War II, Thelma was allocated ZL2JO, the callsign she held until her passing to the hall of silent keys. Thelma was a very active amateur operator during her career as a YL ham; she participated in the Eyeball Amateur Radio network, an American eye-bank net assisting the medical authorities with the transfer of eyes for transplants after accidents or medical emergencies. She was also a founding member of WARO, as well as holding the offices of secretary/treasurer and president over the years.

Florence Voss ZL1AXP, the first president of WARO, became interested in amateur radio when her OM, Sandy ZL1AWA, got his license. Florence was licensed in 1961 and was one of the small group of YLs at the Hamilton conference where WARO was conceived. She reminisces, looking back through her logbook, noting that the net members have increased so much in the ensuing years that there are now three WARO nets, a North Island, a South Island, and a National net, held on Monday nights through the month.

Another early member, Sylvia Kirkland ZL2LS (ex-ZL2QZ and -ZL1BCM) was first licensed in 1954, but her interest in radio goes back to 1922 when she was at school in Oxford, England. A demonstration at the school took two men two days to set up. They erected a massive antenna and had two large tables in the school hall loaded with gear. They were supposed to be listening to a stage musical relayed from London, but the set had no selectivity and all that could be heard were several CW stations, weather stations, shipping, etc., as well as plenty of static, but very little music. The men gave a talk on radio and how it worked; it was that demonstration which kindled her interest in radio and led her to a ham-operator's call in 1954. Sylvia now lives at Eskdale, a short distance north of Napier, New Zealand, and is still active on the air with the TS-520 her family gave to her for Mother's Day about seven years ago.

AWARDS

The WARO Award mentioned above is outlined here.

General: The certificate depicting "Pania of the Reef" is awarded for contacts on any band, SSB/CW/AM, from the same QTH, but net contacts or contest contacts are ineligible for the award. No QSLs required—send a certified list to: Custodian ZL1OC, PO Box 2088, Whakatane, New Zealand, with sufficient postage (IRCs) for the return of the certificate.

The Legend: An old Maori legend tells how Pania, a young Maori maiden, lured by the siren voices of the sea people, swam out to meet them. When she endeavored to return to her lover, she was transformed into the reef which now lies beyond the breakwater at Napier, New Zealand, and bears her name.

HF Bands: DX stations, work 6 resident ZL WARO members. Contacts to date from June 1, 1969. Endorsements for each additional 6 WARO member stations worked, which can include up to 3 overseas WARO members, are available. VK and ZL, work 6 North Island and 6 South Island WARO members for the basic award. Endorsements for every additional 12 WARO members worked.

Listeners: DX listeners, list 10 QSOs dating from June 1, 1969. Endorsements for each additional 5 QSOs heard. VK and ZL listeners, 20 QSOs heard. Endorsements for every additional 10 QSOs heard.

For those interested in this award, ZL YLs may be found each month on International YL Day, the 6th day of every month, on 14.288 either in QSO or calling on the hour, every hour, from about 0600Z. Good luck, and good certificate-hunting, as it is a very nice certificate to have.

BITS 'N' PIECES

NZART World Communications Activity Day, May 21, 1983, was an outstanding success, even though propagation for DX communication was not as good as it could have been. The 8 stations, ZLs 1/4 and 6/9WCY, operated most modes and most bands during the 24-hour period; the stations worked a total of 10,000+ contacts in nearly 100 countries, and about 300 participating hams and helpers were involved at some time or other during the day. QSLs will be sent from the log sheets for all contacts made with ZL WCY stations on that day, and there is no need for return QSL cards. Arthur Law ZL2HE, NZART vice president and coordinator of WCY Activity Day, 1983, and the New Zealand amateur fraternity thank all the DX and local stations who participated in our WCY day and helped to make it such a great success.

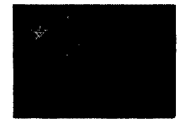
FUTURE HAPPENINGS IN ZL

JOTA, the Jamboree of the Air for the scouting movement, again will be well supported by ZLs in October; we look forward to many good QSOs with other DX stations during the JOTA.

ZL9WCY will be on the air again at a special-event station from the annual Hawkes Bay Agricultural and Pastural Show in October this year. Operating times from the show on 40, 20, 15, or 10 meters, depending upon propagation, will be from 2200Z to 0400Z, approximately, October 19, 20, and 21. The station also could be on the air at other times activated from home stations.

Rose City Conference, 1984: The Annual NZART Conference, 1984, will be held at Palmerston North, New Zealand. For any overseas amateurs who may be touring in this area, the conference will be held over the weekend of June 1-4. Enquiries sent to PO Box 1718, Palmerston North, will be promptly answered. If your holiday plans include ZL-land, we'd like to have you at our conference.

DX News: The Kermadecs, Raoul Island ZL/K, will be activated again soon. Warwick ZL3AFH, currently ZK1WL, Northern Cooks, will be working on Raoul Island for a period commencing later this year, but he will not be properly organized with antennas, etc., until about January, 1984. Warwick, I understand, will be as active as his duties permit and could be on RTTY and OSCAR as well as SSB. More information about the Kermadecs as it comes to hand. It is a rare one and has not been activated for a number of years.



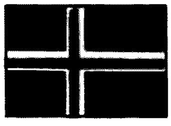
PEOPLE'S REPUBLIC OF CHINA

Rod Hallen KB7NK/DU1
Amembassy-RCPO
APO San Francisco 96528

On 27 May 1983, in the company of Karl K4YT and Jan KG3R, I visited BY1PK in Beijing, People's Republic of China. With the help of an interpreter, we had a long discussion about present and future ham-radio operations in China with Mr. Tong and Mr. Yan. BY1PK is now operating CW only, but plans for SSB operation at some unspecified future date are in the works. BY8AA is also on the air (CW only) from another Chinese province. It is expected that operations will also be started from Shanghai and Guangzhou (Canton) soon, possibly within the next 6 months.

The equipment at BY1PK at the present time consists of a Yaesu FT-107M, a Kenwood-Trio TS-930S, a Canadian 1-kW amplifier, and various clocks, keyers, etc. Antennas which are on top of a 7-story building about 100 feet above ground consist of a rotary Hy-Gain TH6DXX and 2 broadband dipoles. The antenna installations are very heavy-duty and look very professional. The station location is in a new building. Attempts last summer to visit BY1PK were not successful because the building was still under construction at that time. Mr Tong stated that all amateur-radio operators visiting in the People's Republic of China would be welcome to visit BY1PK. Arrangements can be made through the China Radio Sports Association and it would be well to bring your own interpreter since they are not always available at the station location.

When we explained to Mr. Tong, through the interpreter, the meaning of "eyeball QSO," he was quite happy to provide us with BY1PK cards commemorating our visit. When you visit, bring along a few of your own cards, also.



NORWAY

Bjorn-Hugo Ark LA5YJ
Postboks 39, Manglerud
Enebakkveien 208
Oslo 6, Norway

MOBILING IN NORWAY

Norway is a wonderful country to spend your holidays in, especially while mobile operating. As always, plenty of time is essential, but who has enough time to spend on their vacation? It is wise to take it easy and concentrate on one part of the country instead of running through the country at full speed on the highways. That would not be much of a vacation at all. Spend some time in planning the vacation, select certain points to stay for a couple of days or more, and take shorter trips in that specific area.

On most maps, Norway may look little and tiny due to the type of projection used, but on the contrary, it will be nothing like that in reality. As an example, from the southernmost point, Cape Lindesnes, to the northernmost, the well-known North Cape, is over 2600 kilometers—and add another 700 kilometers if you would like to cover the distance to the Russian border. This distance is the same as the distance between Oslo, the capital, and the near-southernmost point in Italy, and bear in mind this is not the road distance, which will turn out to be quite a bit more.

I would suggest visiting the southeast or southwest part or, if the midnight sun is dragging, the northern part of the country. The scenery in any part is worthwhile seeing. Shifting from stony, treeless seasides to fertile green flatlands bulging with grain and vegetables, from endless spruce and pine forests to the wild and naked mountain ranges cut with vigorous valleys, together these form the country we Norwegians are so fond of.

Remember that the country has existed since about the year 1,000, and the oldest city, Tonsberg, is over 1,000 years old, closely followed by Trondheim, which will reach this age around 1990. It seems unbelievable, but all over the country you will very easily find buildings and other sights several hundred years old, with the exception of the northwestern part and northern Norway, where in coastal cities most of the buildings were bombed and burned down during the invasion and retreat of the German army in WWII.

You will find it quite interesting mobiling through a country with so much space for its inhabitants. Even in the city and county of Oslo, three-quarters of the area is covered with forest, wilderness, and farmlands. I wonder how many capital cities around the Western Hemisphere can show off something like that?

Some good advice before starting. Apply for your reciprocal license early so you will be sure to have it on hand before leav-

Take the Drudgery Out of Contesting

Let your Radio Shack computer dupe the log while you relax.

Field Day is over; you've let down the antennas, carted away the gear, and stowed the generator until next year. Now comes the real fun, verifying and checking the log sheets for dupes. Bet you can't wait to get started, can you?

Since Ken and I each purchased a TRS-80 Color Computer™, we have been looking for applications relating to amateur radio. (One gets tired of balancing the checkbook and playing Space Invaders.) After Field Day last year, Ken decided he had found another computer application—and CALLSORT was born. This year, it was used again during Field Day and for other contests. CALLSORT is thoroughly debugged and can assist you when it is time to go over those log sheets.

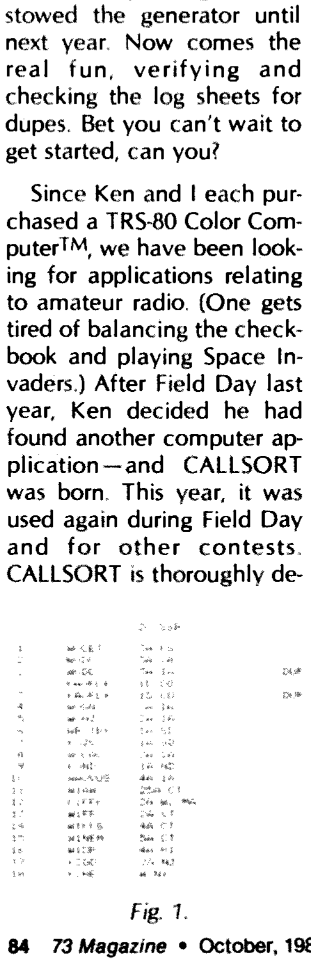

Fig. 1.

The program will let you enter data directly from a log sheet and print a sorted list with or without duplicates on a printer or the CRT. The program handles up to 500 calls if you have a 32K computer. (I probably will never work 500 stations on a single band in my life.) If you have a 16K machine, you will have to modify only lines 20 and 30. When you are done, you can save the log to tape for future reference. You also may stop at any time, save the calls you have entered, and continue entering calls at a later time. This works nicely when you get interrupted by those rare DX calls on 20 meters.

The program is well remarked and should be easy to follow. All remarks may be removed (the REM-line numbers end with a 5). For optimum speed, delete unnecessary spaces when entering the program; they have been left in our listing for easy readability.

One more note, before we look at the program operation in greater detail: In several locations you will find POKE commands. These are used to increase the processing speed of the Color Computer. Just before entering the sort routine in line 170, the computer processing speed is increased. Before tape and printer routines, it must be slowed down again.

Some color computers will not work when you try to increase the speed. If you have never tried this POKE before, *be sure* you save a copy of the program and verify it before you run the program! If the computer "locks up," your machine will not accept the high-speed POKE. To regain control, you will have to press RESET. Control should return to Basic and you should be able to continue work. Just remove the POKEs; the only thing you will lose is a little speed. (If you would like more information on using the high-speed POKE on machines that lock up, send your request and an SASE to Ken W0CZ.

Once the program is typed in and run, you will be prompted for keyboard or tape input. Select the keyboard option. Enter the call, a space, and the section. Fig. 1 is a sample printout of the program; use it as a guide to inputting call data. The numbers on the left are generated by the print routine and are not to be entered from the keyboard. If you make a mistake while entering a call, just press the backspace key. The entire line will be erased and you just reenter the line again.

Once all of the calls have been entered, enter #. You will be asked if you want to save to tape. Then you will be asked if you want a printed list. Just follow the prompts as desired.

The tape file is stored using the contest name. Contest names will automatically be abbreviated to an eight-letter filename. Each tape will contain the band and mode information you enter.

The program is also easily converted to Color Computer disk files. Remove the tape prompts and change all references to buffer #−1 to

Program Listing.

#1 by just deleting the − sign. To convert CALLSORT to run on a Model I or III, the OPEN and CLOSE statements may be deleted. Disk systems should run as is, with the buffer number change. Change all PRINT #−2 references to LPRINT and remove the POKEs.

As you can see by Fig. 1, you can list duplicate entries on the printer. If you want to use the printout to send to the contest authorities, just press <ENTER> when prompted about printing duplicate entries. If you don't have a printer, a sorted list of the calls will be displayed, a screenful at a time. If you are copying them by hand, just press <ENTER> to view the next group of calls.

The program produces a total count of entries—notice that duplicates have the same number on the list. The number by the last call on the list is your total number of valid contacts. To delete a call from the list, read the list in from tape. Enter the number of the call to be deleted as listed on the printout and rewrite the file to tape. You will be prompted for this if you select the INPUT FROM TAPE option 2 at the beginning of the program.

One last comment about the sort. Those who are interested in such things will find the sort routine to be a Basic bubble sort. Though relatively slow, it is infinitely faster than I could sort by hand. Typically, it takes about 3 seconds for the next call on the list to be displayed. I would be interested, though, in hearing from anyone who might improve the performance of this routine.

Ken and I have found that the program takes out just about all of the drudgery of contest logging. Just a few minutes entering the log sheets into the computer is all that is required. The program is especially useful when used by multi-operator stations where duplicates are easily overlooked on multiple log sheets.

If you are like me, you hate to type in long Basic programs. We will send a copy of the program on cassette for $5.00. Specify cassette or disk version, and mail your request to Ken.

A few moments entering this program now will save lots of time after the next contest—time that can be much more profitably used discussing contest results over the local repeater. 73 and happy contesting! ■

World's Fair Super Squelch

With this two-digit DTMF decoder—a perfect club project—you hear only calls meant specifically for you.

Early in the planning stages for the world's fair amateur radio station, WA4KFS, it was decided that a telephone in the station would not be desirable. After all, we wanted to demonstrate the usefulness of radio—and the budget was tight. A telephone seemed out of place. Still, there was a need for a way to get through to the station's control operator without forcing him to monitor a normally busy repeater. Since each of the directors of the Tennessee Wireless Association, the station's sponsor, had touchtone™ capabilities, a touchtone-operated squelch was the obvious answer. The circuit presented here is the one that we used at the fair.

Description

The circuit in Fig. 1

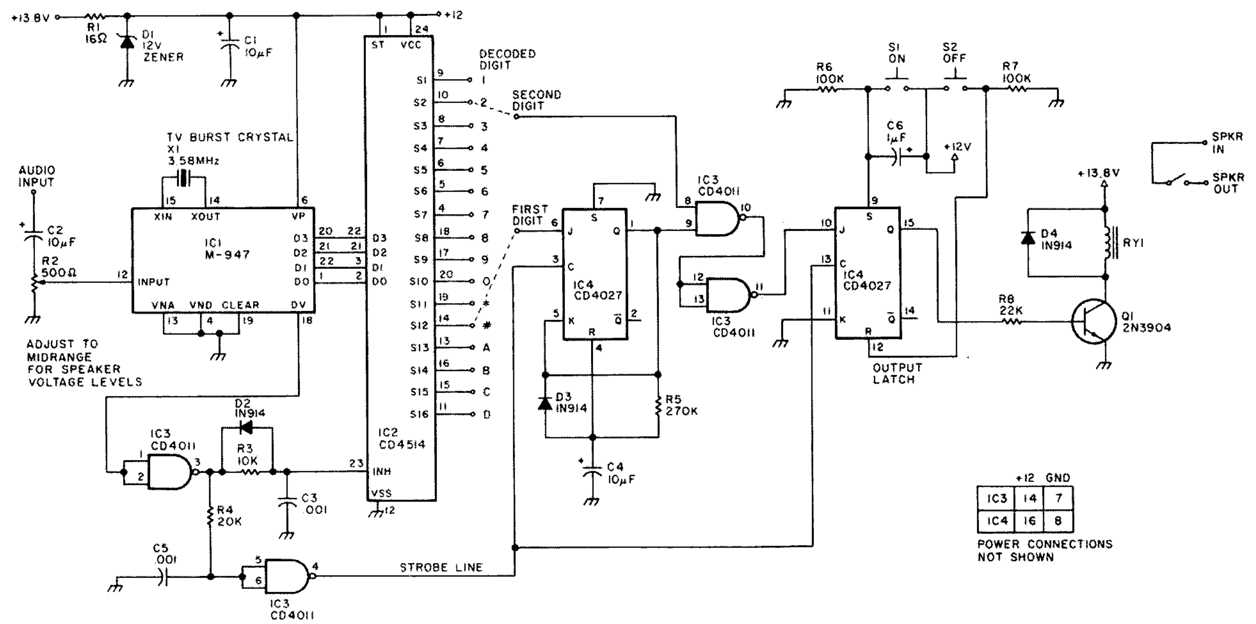

Fig. 1. Touchtone squelch schematic.

makes use of the M-947 DTMF decoder from Teltone, of Kirkland, Washington. The 947 has, on a single IC, all of the filters, amplifiers, and tone detectors needed to detect all 16 touchtone digits and output the corresponding binary codes.

These binary codes are then routed to a CD4514 four-to-sixteen-line decoder 1C which activates a single output line for each touchtone digit. The outputs of this IC should then be connected to the proper stages of the sequence detector corresponding to your desired access code.

Also attached to the 947 decoder are a couple of gates wired as inverters and used with a couple of RC networks to provide delays in strobe-line timing needed to ensure proper clocking of the sequence detector.

The CD4027 dual J-K flip-flop IC is used as a sequence detector. In our case, we needed only a two-digit sequence. However, any number of flip-flops may be wired in series to provide sequence codes of any length. One flip-flop is needed per digit. A four-digit sequence detector is shown in Fig. 2.

Resistor R5 and capacitor C4 form a timer which resets the detector about one second after the first digit of the sequence is received. In this way, not only must the proper sequence be received, but it also must be received in a given time. This guard time may be adjusted for longer sequences according to the formula: Time in seconds = RC/2, where R is in Ohms and C is in microfarads.

The last stage of the sequence detector is the output latch. Attached to its set-and-reset inputs, momentary push-button switches S1 and S2 are provided for local control of the squelch. Pressing S1 will enable the speaker, while pressing S2 will disable the speaker until the next correct sequence is received.

Transistor Q1 is used as a buffer/driver between the output latch and reed relay RY1. Relay RY1 is connected in series with the radio's speaker leads.

One last comment. Since the M-947 is limited to a maximum power-supply voltage of 13.5 V, a 12-volt zener is included to protect the decoder from power supplies with 13.8-volt outputs. Yes, it is *that* critical!

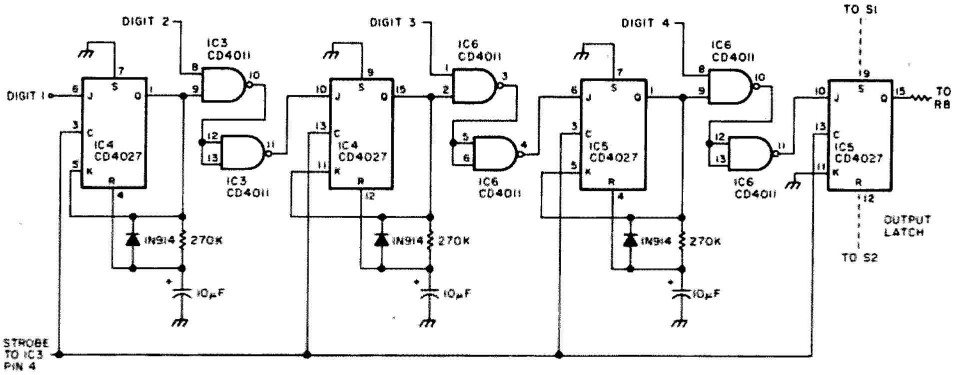

Fig. 2. Four-digit sequence detector.

Construction and Operation

Our two-digit detector was built on perfboard in a Bud CU124 die-cast minibox. It was then wired into the accessory socket of a KDK2025 MK11 2m transceiver.

Before applying power, set your rig's volume control to a normal listening level and then apply power to the circuit. The circuit will always come on in the unsquelched condition. If the opposite is desired, connect capacitor C6 across the off switch, S2, instead of across S1. Now, using another transmitter, send the desired access code to the receiving rig. The speaker will be enabled after the last digit of the access code is released. The speaker then will remain enabled until turned off locally with the off button. Although no circuit for turning off the speaker remotely was included in this design, another sequence detector could be built with its output feeding the K input of the output latch to accomplish this task. ■

Parts List

Designation	Description	Price Each	Total
R1	16 Ohm, ¼ W, 5% (15 Ohm may be used)	.06	$ .06
R2	500 Ohm, ¼ W potentiometer	.59	.59

Defuse RFI

A clean signal starts with a good earth ground. Make yours better with some coax and capacitors.

As a long-time denizen of 10 meters, I have learned along with my like-minded compatriots to suffer when the band is really running well and our friends from 80, 40, and 20 come up to partake of the fun and games. Suffer? You bet!

A ground wire is totally ineffective over 1/8 wavelength on the frequency in use. Dc yes; rf no. This works out to about 4 feet on ten. I realize it is extremely difficult to achieve a situation where your ground wire is 4 feet or less, *to the earth,* not the toilet!

Another problem (coincidental with the above) is rf feedback in the TX audio which in its least annoying form makes your voice sound like vibrating chicken wire and in its worst sends spurs running 100 kHz up and down from your center frequency (or from dc to daylight, as we used to say in Navy ECM).

For considerably less than $5.00, there are steps to take that can result in hearing, either while in QSO or afterwards when the station you worked is talking with someone else, "Lord, that guy in—had beautiful audio!" These measures are not new, but like so many other pieces of hands-on know-how, need to be repeated and correlated every now and then to refresh and instruct those who don't read electronics books on the john.

If your rig is in the basement, effect a ½" 45° hole in the wall with a masonry bit or star drill and drive a 6- to 8-foot ground rod, leaving about 5 inches protruding. Seal with waterproof putty or silicone. Properly placed, this will give you about a 1-foot ground connection. For those not in the basement, a coaxial ground[1] is needed. This is a simple miracle that makes your effective ground length only a few inches!

A coax ground is made using *good* quality (95% shield braid) coax such as Columbia 1107 or 1108 RG-8X or Mini-8 with a stranded center conductor. The center conductor is used as the ground wire, connected to the *rf generating unit* and the outside ground system. It's by-passed at each end with a .01-uF, 1-kV disc capacitor to the shield braid (see Fig. 1). Don't tie all of your station's components together with zip cord or aluminum wire. Let the coax shield handle the dc grounding between units as it is seldom over a foot or so long. Otherwise you set up ground rf loops that defeat everything you've done.

Microphones seem to be universally designed for use in high school auditoriums, with no rf suppression whatsoever. This is simple, so simple that there is absolutely no excuse for rf feedback in this area. All that is usually necessary is to install a .01-uF disc capacitor across the microphone cartridge (do it quickly, because it can't take much heat!) and add a 1-mH choke in series with the audio high lead. This may be done at the mike or on the inside of the mike jack of the transmitter, which is more convenient when using several microphones. If using a power mike, ferrite beads on the transistor base leads and a "pi" filter using two .005-uF capacitors with a 1-mH choke is called for (Fig. 2).

In summation, there is absolutely no excuse for the cruddy signals on HF, and if you're not going for the solution, you're certainly part of the problem. These steps will also knock an RFI problem in the ditch. ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

WOODBRIDGE NJ
OCT 1

The De Vry Technical Institute Amateur Radio Club will hold its annual flea market on October 1, 1983, from 9:00 am to 4:00 pm, in the school parking lot, 479 Green Street (between Rtes. 1 and 9), Woodbridge NJ. Admission is $3.00 for sellers and free for buyers. No electricity will be available. For further information, contact Frank Koempel WB2JKU, De Vry Technical Institute, 479 Green Street, Woodbridge NJ 07095.

SYRACUSE NY
OCT 1

The Radio Amateurs of Greater Syracuse (RAGS) will hold their annual Hamfest and Computer Display on Saturday, October 1, 1983, from 9:00 am to 6:00 pm, at the Art and Home Center, New York State Fairgrounds, Syracuse NY. Admission is $3.00 at the door. Featured will be commercial exhibitors, a large indoor and outdoor flea market, tech talks, an ARRL booth, displays, women's activities, contests, and entertainment. Hot food and beverages will be served. Talk-in on .90/.30, .31/.91, and .52 simplex. For further information, contact RAGS, Box 88, Liverpool NY 13088.

WARRINGTON PA
OCT 1-2

The Pack Rats (Mt. Airy VHF ARC) cordially invite all amateurs and their friends to the 7th annual Mid-Atlantic VHF Conference which will be held on Saturday, October 1, 1983, from 9:00 am to 5:00 pm, at the Warrington Motor Lodge, Route 611, Warrington PA, and to their 12th annual Pack Rat Hamarama on Sunday, October 2, 1983, at the Bucks County Drive-In Theater, Route 611, Warrington PA. The conference will feature an all-day VHF program, a cocktail hour and get-together at 6:30 pm, and a buffet dinner ($12.00 each) at 7:30 pm. Conference registration is $5.00 at the door and includes admission to the Hamarama. Admission to the Hamarama flea market on Sunday is $3.00 and tailgating is $5.00. The gate will open at 7:30 am, rain or shine (bring your own tables). Talk-in on 146.52 MHz (W3CCX). For further information, contact Lee A. Cohen K3MXM, 8242 Brookside Road, Elkins Park PA 19117, (215)-635-4942.

ROME GA
OCT 2

The Coosa Valley ARC will sponsor the Rome Hamfest on Sunday, October 2, 1983, at the Rome Civic Center, Turner-McCall Boulevard, Rome GA. A barbecue and all the trimmings will be available. For further information, contact Libbie Steadham WD4PTE, 18 Poplar Street, Rome GA, or phone (404)-291-4658.

ROCK HILL SC
OCT 2

The 32nd annual Rock Hill Hamfest will be held on October 2, 1983. For further information, contact YCARS, Box 4141 CRS, Rock Hill SC 29730.

CEDAR RAPIDS IA
OCT 2

The Cedar Valley Amateur Radio Club (WØGQ) will hold its 9th annual ARRL CVARC Hamfest on Sunday, October 2, 1983, beginning at 7:00 am, at the Hawkeye Downs Exhibition Building, Cedar Rapids IA. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 for the first and $7.00 for others. There is an overnight camping area, picnic facilities, ample parking, and a concession stand. There will be movies, manufacturers, dealers, and ARRL representatives featured. Talk-in on 146.16/.76, .52, and 223.34/.94 MHz. For advance tickets or reservations, write CVARC Hamfest, PO Box 994, Cedar Rapids IA 52406.

YONKERS NY
OCT 2

The Yonkers Amateur Radio Club will sponsor the Yonkers Electronics Fair and Giant Flea Market on Sunday, October 2, 1983, from 9:00 am to 4:00 pm, rain or shine, at the Yonkers Municipal Parking Garage, corner of Nepperhan Avenue and New Main Street, Yonkers NY. Admission is $2.00 each and children under 12 will be admitted free. Gates will be open to sellers at 8:00 am and there will be a $6.00 admission per parking space which will also admit one (bring your own tables). Refreshments, free parking, and sanitary facilities will be available, as well as unlimited free coffee. There will be live demonstrations all day and a giant auction at 2:00 pm. Talk-in on 146.265T/146.865R or .52 direct. For more information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

ORLANDO FL
OCT 7-9

The second of two Great Southern Computer and Electronics Shows will be held on October 7-9, 1983, at the Orlando Expo Center, Orlando FL. Features will include computer hardware and software, peripherals, accessories, and word and data processing. Exhibits will include commercial and personal electronics, video products, robotics, and communications equipment. There will also be classes, workshops, seminars, and panel discussions. For registration information, exhibitors and attendees should contact Great Southern Computer and Electronics Shows, PO Box 655, Jacksonville FL 32201, or phone (904)-384-6440.

DEERFIELD NH
OCT 8

The Hosstraders will hold their annual autumn swapfest on Saturday, October 8,

MEMPHIS TN
OCT 8-9

Six Memphis radio clubs will sponsor the Memphis Hamfest on Saturday and Sunday, October 8-9, 1983, at the Mid-South Building, Memphis Fairgrounds, Memphis TN. There will be computer displays, software, radio displays, and a flea market (tables on site). Dealers and flea-market sellers may set up on Friday evening, October 7th, until 9:00 pm. Activities will include radio and computer forums, women's programs, and a hospitality party on Saturday night. There will be on-site hookups. Talk-in on .28/.88 and .34/.94. For reservations or more information, contact Clayton Elam K4FZJ, 28 No. Cooper, Memphis TN 38104, or phone (901)-274-4418 (daytime) or (901)-743-6714 (nighttime).

VIRGINIA BEACH VA
OCT 8-9

The 8th annual Tidewater Amateur Radio Hamfest/Computer Convention/Electronic Flea Market will be held on Saturday and Sunday, October 8-9, 1983, at the pavilion at Virginia Beach VA. For both days, the admission is $4.00 and the hours are 9:00 am to 5:00 pm. Flea-market tables are $5.00 for one day and $8.00 for both days; for commercial dealers for both days, table space in the exhibition area is $15.00 and booths are $30.00. Features will include dealers, special displays, forums, computers, and satellite equipment. For tickets and more information, write Jim Harrison N4NV, 1234 Little Bay, Norfolk VA 23503, or phone (804)-587-1695.

BOSTON MA
OCT 8-10

PC '83, an international conference and exposition featuring IBM personal computers and compatibles, will be held on Saturday, Sunday, and Monday, October 8-10, 1983, from 10:30 am to 5:30 pm daily, at the Bayside Exposition Center, Boston MA. A three-day exhibit-and-conference ticket is $25.00 and a one-day exhibits-only ticket is $10.00. Features will include PC application discussions, technical information, and general sessions for IBM PC users. For more information, write Northeast Expositions, 822 Boylston Street, Chestnut Hill MA 02167, or phone (617)-739-2000, or (800)-841-7000 (outside Massachusetts).

WAUKESHA WI
OCT 9

The Kettle Moraine Radio Amateur Club will hold its annual Ham, Computer, Video Fest on Sunday, October 9, 1983, at the Waukesha County Expo Center, Highways F and FT, Waukesha WI. Tickets are $2.00 in advance and $3.00 at the door. Tables are $3.00 for each 4-foot length; reservations will be accepted until September 26, 1983. Since all facilities will be indoors, the hamfest will be open rain or shine, beginning at 8:00 am. There will be food available and commercial exhibitors. For reservations, send a check (payable) to KMRA Club, PO Box 411, Waukesha WI 53187.

BEDFORD IN
OCT 9

The Hoosier Hills Ham Club will hold its 22nd annual Hoosier Hills Hamfest on Sunday, October 9, 1983, at the Lawrence County 4-H Fairgrounds, 4 miles southwest on US Highway 50, Bedford IN. Registration is $3.00 per person and the swap shop is $2.50 (bring your own tables). The gate will open at 10:00 am on Saturday, Oct 8th, for campers and flea-market setups (registration required). There will be a free fish fry, campfire, entertainment, coffee, and overnight camping on Saturday night. Features will include ladies' free bingo and food served at the hamfest on Sunday. Talk-in on 146.13/.73 and setup on 3910 kHz. For further information, contact Dick Reistter KA9JTZ, Secretary, Hoosier Hills Ham Club, Box 891, Bedford IN 47421.

GRAND LEDGE MI
OCT 9

The Central Michigan Amateur Radio Club and Lansing Civil Defense Repeater Association will hold their annual Hamfair on Sunday, October 9, 1983, from 8:00 am to 3:00 pm, at the high school in Grand Ledge MI (7 miles west of Lansing). Donations for adults are $2.50 and tables are 75¢ per foot. There will be amateur radio equipment, antennas, computers, publications, demonstrations, films, a cafeteria, dealer sales, a swap shop, and handcrafted items. For additional information, write Rowena Elrod KA8OBS, 111 Lancelot Place, Lansing MI 48906, or phone (517)-372-5462, or write Hamfair 83, PO Box 18044, Lansing MI 48901.

LIMA OH
OCT 9

The Northwest Ohio Amateur Radio Club will sponsor the 9th annual hamfest on Sunday, October 9, 1983, beginning at 6:00 am, at the Allen County Fairgrounds, Lima OH (exit 125/126 east, 1 mile from I-75). Admission is $3.00 in advance and $3.50 at the gate; full tables are $6.00 and half tables are $3.50. Camping will be free and electrical hookups are $7.00. Talk-in on 146.07/.67 (primary), 147.63/.03, and 146.52/.52. For more information or reser-

SATELLITES

STS-9 LAUNCH POSTPONED

NASA has announced that the shuttle mission carrying Dr. Owen Garriott W5LFL has been postponed by one month. The launch is now scheduled for Oct. 28 rather than the original date of Sept. 30.

According to the Westlink News Service, the launch has been delayed to give additional time for one of the shuttle data relay satellites to be prepared for the mission.

The satellite is an essential component in Spacelab, a series of experiments that will be conducted on board the shuttle *Columbia* during its mission. Although the satellite was launched during a previous shuttle flight, it was behind schedule in achieving the necessary geostationary orbit.

The ARRL has released the operating frequencies for Dr. Garriott's communications with earthbound hams. In North America, hams should listen for him on 145.550 and transmit on 20-kHz channels between 144.91 and 145.090 MHz.

OSCAR 10

Although no Mode L plans have been finalized, use of AMSAT OSCAR 10's Mode B (70 cm uplink, 2m downlink) was scheduled to begin Aug. 6. Unlike previous OSCARs, the new bird remains above the horizon for long periods of time, making reliable VHF/UHF DX possible for the first time in amateur radio.

The band plan for Mode B calls for the lower third of the downlink passband to be reserved for CW, the upper third to be used for SSB, and the center of the passband to be used by both CW and SSB operations. The band plan also reserved Special Service Channels for nets, bulletins, and other scheduled activities.

AMSAT recommends that stations use no more than 750-1000 W erp on the Mode B SSB uplink, and less than that will be necessary for successful CW operation. LSB is the agreed standard for SSB emissions, and right-hand circular polarization should be used for both Mode B and Mode L.

The elliptical orbit of AMSAT OSCAR 10 will also require different tracking techniques than were necessary for the near-circular orbits of previous OSCARs.

Unless specifically designed to include AO-10, run-of-the mill OSCAR locators and programs will not provide correct data for the new satellite. However, programs for many different computers are available from AMSAT for tracking AO-10. Write to AMSAT Headquarters, PO Box 27, Washington DC 20044, for more information.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

VK/ZL/OCEANIA DX CONTEST

Phone
Starts: 1000 GMT October 1
Ends: 1000 GMT October 2

CW
Starts: 1000 GMT October 8
Ends: 1000 GMT October 9

Sponsored by WIA and NZART, the National Amateur Associations in Australia and New Zealand. Use all amateur bands (but no crossband operation is permitted). Only one contact on CW and one contact on phone per band is permitted with any one station for scoring purposes. Only one amateur is to operate any one station under the owner's callsign. Should two or more operate any particular station, each will be considered a competitor and must submit a separate log under his own callsign. This is not applicable to overseas competitors operating club stations.

EXCHANGE:

Send 5 or 6 digits made up from the RS(T) report plus a three digit QSO number starting with 001. Exchange must be acknowledged before points can be claimed.

SCORING:

Stations outside VK/ZL score 2 points per QSO on a specific band with VK/ZL stations. Single-band score will be QSO points for that band multiplied by total VK/ZL call areas worked on that band. Allband score will be total QSO points for all bands multiplied by the total VK/ZL call areas worked on all bands.

AWARDS:

Certificates will be awarded the top scorers in each country (each call area in USA, USSR, and Japan). Depending on reasonable degree of activity, separate awards may be made for top scorers on different bands.

ENTRIES:

Logs must show information in this order: date/time in GMT, callsign of station contacted, band, serial number sent, and serial number received. Underline each NEW VK/ZL call area contacted and make a separate log for each band used. Include a summary sheet to show: callsign, name and address (*please use block letters!*), details of equipment used and, for each band, QSO points for that band and total VK/ZL call areas worked on that band. Failure to remove duplicate contacts will incur heavy penalties, and greater than 2% duplicates will disqualify the entry.

All logs should be posted to: WIA VK/ZL Contest Manager VK3BGW, 1 Noorabil Court, Greensborough, Victoria 3088, Australia. Any logs, even for small numbers of contacts, will be greatly appreciated!

SWL SECTION:

The rules are similar to the transmitting section but it is open to all members of any SWL society in the world. No transmitting station is permitted to enter this section. The contest times and logging of stations on each band per weekend are as for the transmitting section except that the same station may be logged twice on any band, once on phone and on CW.

To count for points, the station heard must be in QSO exchanging data in the VK/ZL DX contest and the following details noted—date/time in GMT, call of the station heard, call of the station he is working, RS(T) of the station heard, serial number sent by the station heard, band, points claimed. Scoring is on the same basis as for the transmitting section and a summary sheet should be similarly set out.

Overseas stations may log only VK/ZL stations, but VK receiving stations may log overseas stations and ZL stations, while ZL receiving stations may log overseas and VK stations. Certificates will be awarded as listed in the section under awards.

CALIFORNIA QSO PARTY

Starts: 1600 GMT October 1
Ends: 2159 GMT October 2

Sponsored by the Northern California Contest Club, with strong efforts being made to have all 58 counties in California on for the contest duration.

Single-operator stations may operate only 24 hours of the contest period; off times must be clearly marked in the log and must be at least 15 minutes long. Multi-operator stations may operate the full 30 hours. Stations may be worked only once per mode per band. All contacts must be simplex. All CW contacts must be made in the CW subband. California stations that change counties are considered to be new stations and may be contacted again for points credit.

EXCHANGE:

CA stations send QSO number and county. Others send QSO number and state, province, or ARRL country.

FREQUENCIES:

Novice—3725, 7125, 21125, 28125.

CW—1805, 3560, 7060, 14060, 21060, 28060.

SSB—1815, 3895, 7230, 14280, 21365, 28560.

Try CW on the half-hour and 160 meters at 0500.

SCORING:

Each completed phone contact is worth 2 QSO points. Each completed CW contact is worth 3 QSO points. For multiplier, CA stations use the number of states, VO/VE 1-7, and VY1/VE8 for a possible of 58. Others use the number of CA counties worked for a possible total of 58. The final score is the number of QSO points multiplied by the total number of multipliers.

AWARDS:

Certificates for highest scoring station in each CA county, each state/province, and each country. Certificates also to each station scoring 100 or more QSOs. Trophies to the highest scoring out-of-state single op, highest scoring CA single op, and highest scoring DXpedition to a CA county by single and multi-ops.

ENTRIES:

All logs and summary sheets must be sent by November 1 to: NCCC, c/o Alan Brubaker K6XO, 34456 Colville Place, Fremont CA 94536. Please include a business-size SASE with your entry.

QSLS:

QSLs to NCCC California stations without an SASE will be responded to via the QSL Service (USQS), PO Box 814, Mulino OR 97042. This will enable CA stations to confirm contest QSOs at minimum expense to all concerned. To claim these and other QSLs from USQS, send a business-size SASE to USQS. For further details, send an SASE to USQS or see any issue of *World Radio News*.

OREGON QSO PARTY

1700 GMT October 1 to
0800 GMT October 2
1500 GMT October 2 to
0000 GMT October 3

Sponsored by the Hermiston Amateur Radio Club. Operating categories include mixed mode or CW only. Each station may be worked once per band and once per mode.

CALENDAR

Feb 18-19	America Radio Club International DX Contest

Beaver County QRM

NEWSLETTER OF THE MONTH

Beneath the full masthead of this newsletter (part of which is above), if you look closely, you can make out the words "Founded: 1922." Here's a club with history, and the members of the Beaver Valley Amateur Radio Association have not forgotten their spark-gap roots.

The *Beaver County QRM*, edited by Joseph Ross KF3X, is a newsletter the club's founders could be proud of. Editor Ross ensures that the newsletter does not merely inform but entertains as well, and part of his editorial repertoire stems from the club's long history. Features such as "Club Capsule," which reincarnates the news of 40 years ago, remind members of their heritage.

The June issue also included a reprint of minutes from the club's 11-member reorganizational meeting in 1946. Less than 10 years later, the club incorporated, evidence of its strong post-war growth.

Ross does not limit the *QRM* to Beaver Valley club news only. Through the newsletter, he keeps members up to date on other news, too—such as an interview with ARRL Atlantic Division Director Hugh Turnbull on volunteer exams and no-code licenses. He also culls the best from other newsletters, such as the Indiana County ARC's *Sine of the Times* and the Triple States Radio Amateur Club's *BNT*, and reprints them in the *QRM*. And for those whose interests fall in areas outside of ham radio, Ross has thoughtfully included some interesting no-ham features. "If You Are A Beer Drinker and Like to Keep Your Weight Down" is (or should be) of particular interest to the summertime ham.

So if you want to know not only the latest FCC regs or satellite news, but also the number of calories in 807 Ale—*Beaver County QRM* is for you

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send a copy to *73*, Pine Street, Peterborough NH 03458.

EXCHANGE:

Signal report and state, province, country, or OR county.

FREQUENCIES:

Phone—1810, 3829, 7260, 14300, 21370, 28600.

CW—80 kHz up from bottom of each band.

Novice—10 kHz up from bottom of each Novice band.

SCORING:

Count one point per QSO. OR stations multiply QSO points by the sum of states, provinces, countries, and OR counties. All others multiply by the sum of OR counties worked (36 max).

ENTRIES AND AWARDS:

All entries must have a log and summary sheet. Official sheets are available from KA7IXH for an SASE. Logs must be received by November 4 and should be addressed to Bob Franklin KA7IXH, Rt. 3, Box 3783, Hermiston OR 97838. Include a large SASE for a copy of the results.

MARYLAND-DISTRICT OF COLUMBIA QSO PARTY

Starts: 1800 GMT October 15
Ends: 2100 GMT October 16

Sponsored by the Columbia Amateur Radio Association, the contest is open to all single-operator stations. The same station may be worked on each band and mode.

EXCHANGE:

QSO number, RS(T), and state, province, country, or MD county. Remember

Northern Alberta CC	1026366
Texas DX Society	946410
River City Contesters	329004
Sturdy Mem. Hospital ARC	147912

that Baltimore and Washington are independent cities!

SCORING:

MDC stations multiply total QSOs by sum of MD counties, states, provinces, and countries. Others multiply MDC OSO total by number of MD counties and independent cities (25 maximum). Also, multiply score by 1.5 if running 200 Watts or less.

FREQUENCIES:

Phone—3950, 7250, 14290, 21390, 28590.
CW—60 kHz up from low end.
Novice—3720, 7120, 21120, 28120.

AWARDS AND ENTRIES:

Maintain a continuous log for phone and CW but indicate on entry which category (phone, CW, or mixed) you are entering. Certificates for top scorers in each category will be awarded. Mail logs, dupesheets (for over 200 contacts) and summary by November 30th to CARA, c/o Robert K. Nauman WA3VUQ, 4017 Font Hill Drive, Ellicott City MD 21043.

MINNESOTA QSO PARTY
1800 to 2300 GMT October 15

Sponsored by the Paul Bunyan Wireless Association. Work stations once per band and mode. Repeater QSOs are not allowed.

FREQUENCIES:

Phone—3890, 7230, 14280, 21375, and 28875.

CW—40 kHz up from low end of the band.

Novice—25 kHz from the low end of the band.

EXCHANGE:

Exchange signal report and QTH (county for Minnesota stations; state, province, or country for others).

SCORING:

Count 1 point for each phone QSO and 2 points for each CW QSO. MN stations multiply total QSO points by the sum of the number of states worked. Other stations multiply by the total of Minnesota counties worked (maximum, 86). Add 100 bonus points if you work 10 Minnesota counties.

ENTRIES:

Entries must be mailed no later than November 1, 1983, to PBWA, Steve Scott KCØUJ, 801 6th St., Staples MN 56479.

JAMBOREE ON THE AIR
Starts: 0001 GMT October 16
Ends: 2400 GMT October 17

This is the 26th annual Scouting/ham radio event sponsored by the World Scout Bureau, Geneva, Switzerland. Boy Scouts and Girl Scouts of all ages, from Tiger Cubs through adult Scouters, and anyone interested in Scouting and ham radio are welcome. If you have never been a Scout, talk to some Scouts about amateur radio and give them the thrill of talking to you. There should be activity from about 100 countries, just enough for DXCC! The World Bureau station, HB9S, the BSA station, K2BSA, and many camporee and special-event stations will also be operating.

The exchange is just good Scout talk about Scouting experiences, ham radio, and friendship greetings, many of which may lead to lasting pen-pal exchanges.

FREQUENCIES:

Scout frequencies published by the World Bureau are as follows:
Phone—3940, 7290, 14290, 21380, 28990.
CW—3590, 7030, 14070, 21140, 28190.
Novice—SSTV and RTTY on usual frequencies.

Postcard-size certificates issued by the World Bureau are available to anyone participating in any manner. Send SASE to: Boy Scouts of America, International Division/JOTA Cards, 1325 Walnut Hill Lane, Irving TX 75062-1296 (twenty cents affixed postage for up to 8 cards and 17 cents for each additional 8 cards). Cards/certificates may be ordered before the event for distribution during JOTA activities or after.

A distinctive temporary insignia pocket patch is available for the first time, for wear on the Scout uniform, at $1.00 per patch, postpaid, any quantity. Send personal check or money order (no stamps) to BSA, International Division/JOTA PATCH, at the same address as above. Checks should be made out to: Boy Scouts of America. Please send separate orders for certificates and patches.

Logs or lists of participants are *not required*, but reports of activity, news articles, bulletin announcements, narrative reports of activity, and photos are welcome for inclusion in the BSA report to the World Bureau and possible use in Scout publications. Send them to the JOTA Coordinator W2GND, 218 Maxwell Avenue, Hightstown NJ 08520.

PENNSYLVANIA QSO PARTY
1600 GMT October 22
to 0500 GMT October 23
1300 GMT October 23
to 2200 GMT October 23

Sponsored by the Nittany Amateur Radio Club. CW contacts must be in the CW subbands. Stations may be worked once per mode (phone and CW) on each band. Mobiles may be reworked as they change counties. Repeater contacts are not permitted.

There are four classes of entry: single operator with no assistance allowed, fully mobile (multi-op OK), multi-operator with single transmitter and no spotting receivers, and multi-multi where anything goes.

EXCHANGE:

RS(T), 3-digit sequential serial number, and ARRL section or PA county. Stations on county lines will give out one number but the two counties will count as two separate multipliers.

FREQUENCIES:

SSB—3980, 7280, 14280, 21380, 28580.

CW—40 kHz up from bottom of CW bands.

Novice—10 kHz up from bottom of Novice subbands.

Try 160 meters CW on 1810 at 0400 GMT and SSB on 1835. New WARC bands are not permitted.

SCORING:

Count 1 point for SSB QSOs, 1.5 points for CW QSOs, and 2 points for 160- and 80-meter CW QSOs. PA stations multiply QSO points by the total number of ARRL sections plus the total number of PA counties plus a maximum of one DX country (142, total maximum). Others, multiply QSO points by the total number of PA counties worked (67, maximum).

AWARDS:

Plaques for top scorers in both eastern and western PA, top out-of-state station, top mobile station (assuming at least 3 entries), and top multi-operator entry. Revolving trophy to the club with the top aggregate score from membership. Certificates to winner in each county, each section with a minimum of 20 QSOs, and winner in each club with a minimum of 3 entries.

Special awards to the first station which scores 150,000 points (single operator), 2,000 QSOs (any class), 200,000 points (multi-single), 500 QSOs (out of state), 1,000,000 points (club competition), and all the 67 counties in the contest.

ENTRIES:

Logs must be submitted on official forms or on reasonable duplicate. Also include a dupesheet for entries with over 100 QSOs. For each dupe QSO removed by checkers 100 points will be deducted from your final score. Illegible logs will be treated as check logs. Send logs no later than November 25 to Douglas R. Maddox W3HDH, 1187 S. Garner Street, State College PA 16801. Note: Please include $0.50 postage for results!

QRP ARCI
FALL QSO PARTY
Starts: 1200 GMT October 22
Ends: 2400 GMT October 23

The contest is open to all amateurs and all are eligible for the awards. Stations may be worked once per band and mode for QSO and multiplier credits. Partici-

pants may operate a maximum of 24 hours during the contest period.

EXCHANGE:

Members—RS(T), state, province, or country, and QRP ARCI membership number.

Non-members—RS(T), state, province, or country, power output.

SCORING:

Each member QSO counts 5 points regardless of location. Non-member QSOs are 2 points with US and Canadian stations; others, 4 points each. Multipliers are as follows: 4-5 Watts output CW or 8-10 Watts output PEP—×2, 3-4 Watts output CW or 6-8 Watts output PEP—×4, 2-3 Watts output CW or 4-6 Watts output PEP—×6, 1-2 Watts output CW or 2-4 Watts output PEP—×8, and less than 1 Watt CW or 2 Watts output PEP—×10.

Entries from stations running more than 5 Watts output CW or 10 Watts output PEP will count as check logs only. Stations are eligible for the following bonus multipliers: if 100% natural power (solar, wind, etc.) with no storage—×2; if 100% battery power—×1.5.

Final score is total QSO points (total all bands) times total number of states, provinces, or countries times the power multiplier and times the bonus multiplier, if any.

FREQUENCIES:

CW—1810, 3560, 7040, 14060, 21060, 28060, 50385.

SSB—1810, 3985, 7285, 14285, 21385, 28885, 50385.

Novice/Tech—3710, 7110, 2110, 28110.

No 30-meter contacts will be counted.

AWARDS:

Certificates to the highest-scoring station in each state, province, or country with 2 or more entries. Entries automatically considered for annual Triple Crowns of QRP Awards.

LOGS AND ENTRIES:

Separate log sheets are suggested for each band for ease of scoring. Send full log data plus separate worksheet showing details and time(s) off the air. No log copies will be returned. All entries desiring results and scores please enclose a business-size envelope with return postage for one ounce or an IRC.

It is a condition of entry that the decision of the QRP ARCI Contest Chairman is final in case of dispute. Logs must be received by November 20th to qualify. Logs received after that date or missing information will be used as check logs. Send all logs and data to William W. Dickeron WA2JOC, QRP ARCI Contest Chairman, 230 Mill Street, Danville PA 17821.

CLARA AC-DC CONTEST
Starts: 1800 GMT October 22
Ends: 1800 GMT October 23

Sponsored by the Canadian Ladies Amateur Radio Association, the Ac-Dc Contest is open to all YL and OM amateurs. Each station may be worked twice, either once on CW and once on phone, or on two different bands.

EXCHANGE:

Signal reports, QTH, and name. Bonus stations will operate in each province and will identify!

FREQUENCIES:

Phone—3900, 3775, 7150, 14280, 14160, 21300, 28588, 28488.

CW—3690, 7035, 14035, 21035, 28035.

SCORING:

CLARA members score 1 point per contact with non-members, 2 points per CLARA member contact, and 3 points per bonus station. Multiply by two for contacts made on CW. Multiply total of the above by the number of Canadian provinces/territories worked for total score. Non-CLARA members count points the same except only CLARA member contacts are to be counted.

AWARDS:

First place, CLARA Cup, and certificate to first-place CLARA winner, certificates to second and third. Plaque and certificate to first-place non-CLARA winner, certificates to second and third.

ENTRIES:

All logs submitted are eligible for the mini-prize drawing. Mail all logs and scores with your name, call, address, and postal code by December 15th to Muriel Foisy VE3LQH, Box 122, Janetville, Ontario, Canada L0B 1K0.

MF RUNDE SW ACTIVITY WEEKEND
Starts: 0400 GMT October 22
Ends: 2200 GMT October 23

The society of hamming ex-naval radio operators (MF Runde) offers this SW activity weekend for the easier application of the society awards. Every licensed ham is invited to take part, but QSOs must be between MF members and non-members. No club stations are permitted—only single-operator stations. Use all bands except the new WARC 10-, 18-, and 24.9-MHz bands, using CW and/or SSB.

This is the second weekend of activity. The official rules were received too late to publish before the first weekend in April.

The society club stations, DL0MF and DL0MF/A, are coordinating the traffic: Every full hour they pile up competitors (MF members and non-members) on SSB and divert them to frequencies where MF members are QRV for QSOs. Every 30 minutes after the hour they do the same thing with CW competitors. The advantage is that the club stations are able to tell competitors what MF members within the next hour are QRV. Every 3 hours the working frequencies are changed. General call for all is "CQ MF."

EXCHANGE:

RS(T) for non-members, RS(T) and MF number for members.

SCORING:

Every MF member worked on CW counts 2 points; on SSB, 1 point. QSOs with DL0MF on CW are 10 points or 5 points on SSB. QSOs with DK0MG and DK0DW are 6 points on CW and 3 points on SSB. Remember that every MF member can be worked on SSB and CW; that means 3 points for both contacts! Final score is the sum of QSO points.

AWARDS:

Awards are issued for 50 points (bronze), 100 points (silver), 150 points (gold), and 250 points (trophy). Awards for CW-only operation will have special engraving! For further information on award rules and MF membership lists, please send addressed envelope and IRCs to award manager.

ENTRIES:

Every operator is asked to send his signed logs no later than November 15th to Kurt Wuestner, Award Manager, PO Box 25, D-4600 Dortmund, Federal Republic of Germany. Award applicants outside the Federal Republic should use a GCR list and add 20 Deutschmark in cash or equivalent value. Logs must show callsign, name, and home address, plus date/time in GMT, band, station worked, and exchanges sent and received.

HELVETIA 26 AWARD

This award has been instituted by the Union of Swiss Short Wave Amateurs (USKA) with the object of furthering friendly relations and the competitive spirit between its members and radio amateurs abroad.

Foreign amateurs must submit QSL cards showing evidence of contacts with stations in each of the 26 cantons and half-cantons of the Swiss Confederation on any bands between 1.8 and 30 MHz.

All contacts claimed must be made on or after January 1, 1979. Cross-mode contacts will not be valid. Awards will be offered for all phone, all CW, phone/CW mixed mode, radioteletype (RTTY), and slow-scan television (SSTV).

QSL cards submitted must clearly show the location (canton) of the Swiss station at the time of contact. Any QSL card from a Swiss station operating from a temporary or portable location at the time of the contact must show the canton of such location in order to be recognized as a valid contact.

In addition to QSL cards, applicant must submit a signed list of all contacts in alphabetical order by canton, include the station's callsign, date and time in GMT, band and mode of operation, and RS(T).

The 26 cantons are as follows: AG—Aargau, AI—Appenzell Inner Rhoden, AR—Appenzell Outer Rhoden, BE—Berne, BL—Basel Country, BS—Basel City, FR—Fribourg, GE—Geneva, GL—Glarus, GR—Grisons, JU—Jura, LU—Lucerne, NE—Neuchatel, NW—Nidwalden, OW—Obwalden, SG—Saint Gall, SH—Schaffhausen, SO—Solothurn, SZ—Schwyz, TG—Thurgau, TI—Ticino, UR—Uri, VD—Vaud, VS—Valais, ZG—Zug, ZH—Zurich.

The applications for the award must have sufficient postage enclosed in the form of IRCs to allow the safe return of your QSL cards.

Mail your application to the attention of Walter Blattner HB9ALF, PO Box 450, 6601 Locarno, Switzerland.

STATE CAPITALS AWARD

The Newark News Radio Club of Newark, New Jersey, takes pleasure in announcing its sponsorship of the SCA (State Capitals Award), which is available to licensed amateurs throughout the world for working stations located in state capital cities of the United States on or after January 1, 1960. This award is also available to shortwave listeners on a "heard" basis.

The purpose of this award is to offer recognition for operating achievements and to offer still another worthwhile contribution to the field of competitive radio-amateur operation.

It is hoped by the directors, officers, and members of NNRC that amateurs everywhere will accept the award as a gesture on the part of the sponsor to further promote and expand goodwill and better understanding among amateur operators and shortwave listeners.

The State Capitals Award is offered in three (3) classes: Class C—work 30 state capital cities; Class B—work 40 state capital cities; Class A—work 50 state capital cities.

There are no band or mode endorsements. Cross-mode contacts will not be valid.

To apply, applicants should prepare a list of contacts claimed, listing them in alphabetical order by US state. Include the usual logbook information for each contact. Have this list verified locally by two amateurs, a local radio club secretary, or a notary public. Do not send QSL cards. Have your verified list sent along with the $1.00 award fee to S. J. Knox WB2MRA, 212 North Jerome Avenue, Margate, New Jersey 08402.

DIPLOME DES 100

This award is given by the ITU to radio amateurs and shortwave listeners everywhere in recognition of their achievement in communicating with, or logging the reception of, amateur-radio stations in the territory of 100 or more member administrations of the ITU. Any licensed radio amateur or shortwave listener is eligible for this award. It is given to the individual, and the qualifying contacts may be made over any period of time subsequent to the dates shown in the ITU official countries list available from the awards manager.

Applications shall be made by letter and shall include a list of stations claimed in alphabetical order, showing claimed dates. No special form is required for this purpose. Only frequencies, modes, and prefixes approved by the Radio Regulations of the ITU may be used. To qualify, 100 or more contacts must be made.

QSL cards or proper log entries will be considered proof of contact to back up an award application. Attached to the application should be a statement from two licensed amateurs or an ITU administration representative to the effect that all claimed contacts have been verified. No other proof is required. Do not send QSL cards! Do not send logs!

There will be no endorsements for special conditions. Stickers will be given for each ten (10) additional contacts.

The administration of this award has been delegated to the International Amateur Radio Club, 4U1ITU, PO Box 6, 1211 Geneva 20, Switzerland. The IARC has

named Mr. L.M. Rundlett K4ZA as awards manager. All applications should be accompanied by 10 IRCs or US $2.00 for the award, and one IRC or a US self-addressed, stamped envelope for each sticker. Mail all applications to L.M. Rundlett K4ZA, Route 3, Box 447, Lake Placid FL 33852.

AWARDS FROM MOSCOW

I received a very complete package of information from the Central Radio Club in Moscow and take pleasure in featuring their award program in more detail. It is unfortunate they did not send samples of their certificates, as I'm sure they are unique diplomas to possess.

R-100-0 Award

This award (as is the case for all awards listed below) is issued to all licensed radio amateurs and shortwave listeners throughout the world who can meet the requirements. For the R-100-0, radio amateur applicants must carry out two-way contacts with, and shortwave listeners must log reception reports of, radio stations in 100 oblasts (provinces) of the Soviet Union.

There are three categories of R-100-0 awards. The First Class is for two-way contacts on the 3.5-MHz band only, the Second Class is for two-way contacts on the 7-MHz band only, and the Third Class is for two-way contacts on any amateur band. All contacts must be made on phone or CW only. Endorsements will be given for each mode of operation, but cross-mode or mixed-mode contacts are not allowed. All reports exchanged between stations must be RST 337 or RS 33 as a minimum. All contacts or observations must be made on or after January 1, 1957, to be valid.

Applications must include a list of contacts or observations with date, calls, mode, and frequency shown in order of callsign prefix. QSL cards must be submitted along with the award fee of one ruble or 14 IRCs to cover the cost of the award and safe handling of your QSL cards back to you. One should allow three to six months for the processing of any of the awards I am describing. Send all applications and inquiries related to this or any of the following awards to The Central Radio Club USSR, Postbox 88, Moscow, USSR.

W-100-U Award

The W-100-U Award (worked 100 radio stations in the USSR) was established in 1959 on the 100th anniversary of the birth of A.S. Popov, the great Russian scientist claimed to be the inventor of radio. For this award, amateurs must carry out two-way contacts on one or more amateur bands with 100 different amateur stations of the Soviet Union, including 5 radio stations of the 9th region (Minskaya). All contacts must be on either phone or CW, and applications must state which mode is to be credited for the award. Cross-mode or mixed-mode contacts do not count. All contacts must have been made January 1, 1959, or after and all signal reports exchanged must be at least RS 33 or RST 337 to be claimed. As with the R-100-0 award, the applicant must prepare a list of contacts claimed and give the calls, date, frequencies, and type of emissions used to achieve the contacts. The cost of the award is 1 ruble or 14 IRCs, to be sent with your application, and QSL cards are required. The award fee is used to provide for the safe return of your confirmation cards.

R-6-K Award

The worked-all-six-continents award is offered by the Central Radio Club to amateurs and to shortwave listeners who can carry out 12 two-way contacts or observations on SSB, CW, and phone with radio amateurs as follows: one contact each in Europe, South America, Africa, Asia, North America, and Oceania, plus 3 contacts each in the European USSR (UA1, UN1, UW1, UA2, UC2, UP2, UQ2, UR2, UA3, UW3, UV3, UA4, UW4, UB5, UO5, UT5, UY5, UA6, or UW6) and the Asiatic USSR (UD6, UG6, UF, UL7, UI8, UJ8, UH8, UM8, UA9, UW9, UV9, UA9, or UW0). The award has three categories: First Class is for two-way contacts on 3.5 MHz only, Second Class is for two-way contacts on 7 MHz only, and Third Class is for two-way contacts on any amateur band. As with all awards of the Central Radio Club, confirmation cards must be sent with your application. To qualify, all contacts must have been made May 7, 1962, or after. The award fee is 1 ruble or 14 IRCs, the same as it is for each of the awards of the Central Radio Club.

R-10-R Award

The R-10-R Award (worked 10 radio amateur regions in the USSR) is available to those who carry out, on one or more amateur bands, two-way contacts with 10 radio amateur regions in the USSR. These regions may also be termed call districts; in any case, numbers one (1) throughout zero (0) must be worked. All contacts must be made on either phone or CW. Mixed-mode or cross-mode contacts will not count. All contacts must be made after July 1, 1958, and signal reports must be a minimum of RST 337 or RS 33. The submission of applications and the cost of the award is the same as noted with the other awards in the Central Radio Club portfolio.

R-15-R Award

The R-15-R Award (worked radio stations in 15 USSR Republics) is offered to those who work at least 15 of the 18 USSR Republics within a period of 24 hours. They are: European Russian SFSR, Franz Josef Land, Kaliningradsk, Asiatic Russian SFSR, Ukraine, White Russian SFSR, Azerbaijan, Georgia, Armenia, Turkoman, Uzbek, Tadzhik, Kazakh, Kirghiz, Moldavia, Lithuania, Latvia, and Estonia.

All contacts for the R-15-R Award must be made on CW or phone on or after July 1, 1958. Applicant must submit a list of claimed contacts giving date, emission, and frequency for each contact and must provide a QSL card for each contact claimed. Cost and mailing directions are the same as for the other Central Radio Club awards.

R-150-S Award

Probably the most sought-after award in the program offered by the Central Radio Club is the R-150-S Award. Amateurs and shortwave listeners throughout the world are eligible to compete for this award and must complete the following operating requirements to qualify.

The R-150-S Award requires the applicant to work at least 150 countries of the world and 15 Republics of the USSR from a special USSR DX countries listing.

There are no band restrictions, but contacts must be made on either phone or CW. All contacts must be made on or after June 1, 1956. Signal reports exchanged must be a minimum of RST 337 or RS 33.

Submission of applications and cost of the award is the same as noted for the other Central Radio Club awards.

RSES 150

The amateurs of Redford Township, Michigan, invite everyone to help them celebrate their sesquicentennial—150 proud years. This special event station, KG8W, is the culmination of much work by Redford amateurs. The year started with little organization and a station at Thurston High School which had not been on the air in 8 years. For this event, our amateurs have rehabilitated the Thurston station, which consists of a Collins S-Line with 30S1 linear, a Drake TR4C with L4 linear, and a Heath HW16 Novice station. Dave Riley KG8W, who is allowing us to use his call, was one of the last to operate the Thurston station as a student before it was closed down. After this September 24, 0000Z-2400Z event, the station will be operational for use in the Thurston High School electronics program. A specially designed QSL will be returned for your OSL (with contact number) and SASE to: RSES 150, 18800 Beech-Daly, Redford MI 48240. Operating frequencies, dependent on propagation, will be up from 3.6, 3.88, 7.065, 7.215, 14.05, 14.215, 21.09, 21.34, 28.09, 28.6; Novice—bottom 10 kHz of band.

SUNBELT AGRICULTURAL EXPOSITION

The Colquitt County Ham Radio Society will be operating club station WD4KOW from the site of the sixth annual Sunbelt Agricultural Exposition on October 11, 12, and 13, 1983. The hours of operation will be 0900 to 1700 EDST each day.

This annual Sunbelt Expo is held each year at Spence Field Airbase, located near Moultrie, Georgia, and is the largest agricultural show in the south. This event draws over 200,000 visitiors from all over the United States and foreign countries.

Operations will be in the General portion of the HF bands. The members will also be listening for visiting hams on the local repeater (146.19/.79). Visiting hams are invited to visit the amateur booth at the Expo and operate the amateur station. A special QSL card is available for those making contact during this event who submit an SASE.

SUFFOLK COUNTY NY

Suffolk County Radio Club will operate W2DQ from 0000Z October 28 until 2400Z October 30 in celebration of Suffolk County's 300th birthday.

Frequencies: phone—15 kHz up from lower 40-15-meter General-class band edges; Novice—21.135.

For a special certificate, send a large SASE to Richard Tygar AC2P, 5 Chelmsford Drive, Wheatley Heights NY 11798.

NAVY WEEK SPECIAL EVENT STATION

On October 30, 1983, the Laurel, Maryland, Amateur Radio Club will operate K3LDE on board the *USS Constellation* from 1200 to 2200 GMT. Operating frequency will be 7225 with QSY to 14225 and 21400 per band conditions. They request 3 first-class stamps to cover mailing tube and specially-designed certificate. Send requests to: Laurel MD ARC, Box 259, Annapolis Junction MD 20701.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½"×11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye." and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

Vertical Vibroplex and other old keys wanted for a private collection.

Dick Randall K6ARE
1263 Lakehurst Rd.

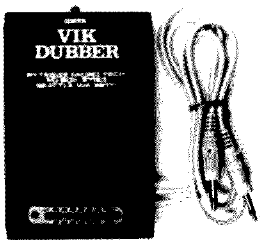
NEW PRODUCTS

BYTESIZE OFFERS A CASSETTE INTERFACE

The VIK-Dubber cassette interface allows VIC-20 and C64 users to save and load data using any standard cassette recorder. The VIK-Dubber circuitry filters and enhances the cassette data, virtually eliminating bad loads. It also includes several features to allow easier cassette use; it allows you to connect two cassette recorders together to make high-quality backup copies of cassette programs, even machine language. An indicator light and quiet audible tone help you to adjust cassette volume for proper use and allow you to monitor the cassette data. The VIK-Dubber gets its power from the computer, so no batteries are needed. It comes in an attractive case, tested and ready for immediate use.

For more information, contact *Bytesize Micro Technology, PO Box 21123, Seattle WA 98111; (206)-236-BYTE.* Reader Service number 481.



The VIK-Dubber cassette interface from Bytesize Micro Technology.

TURNING THE TRS-80 COLOR COMPUTER INTO A CW MORSE-CODE TERMINAL

A recently introduced modem called the KA9FSQ CW modem interface changes the RX tone into a signal pulse. This makes it possible for ham-radio operators to transmit or receive Morse code on their TRS-80 Color Computers.

A visual indicator (signal LED) is mounted on the unit for the indication that you're locked in on the signal and it is being received. While other units use a mechanical relay for TX, the KA9FSQ CW modem uses an optoisolator to keep keying voltages away from your computer and give a clean digital pulse to your transmitter. This unit can also be used with other CW programs with proper software modifications.

The modem is easy to use. Just plug the cartridge into the ROM-PAC slot on the side of your Color Computer and connect two cables, one from your transmitter and one from your receiver. Turn your computer on and CLOAD the program from tape. RUN the program and sit back for Color-Computer Morse.

For more information, contact *Mitronix, 5953 N. Teutonia Avenue, Milwaukee WI 53209.* Reader Service number 478.

NEW CATALOG FROM UNIQUE COMMUNICATIONS

Unique Communications has released its new 72-page catalog of telephones and accessories. This catalog lists a variety of products ranging from desk-type rotary telephones complete with memory dialing, mute switch, and automatic redial. Reconditioned and new telephones are available in many price ranges.

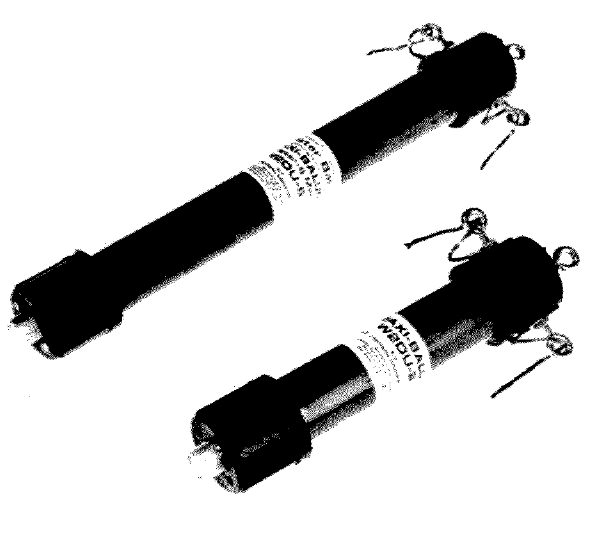
Other telephones available from Unique Communications include one-piece rotary and touchtone phones, Slimline-style phones, and cordless extension phones.

For more information, contact *Unique Communications, 6335 S. R. 97, Galion OH 44833; (419)-468-6972.* Reader Service number 483.

MICROWAVE FILTER CO. "MAXI" BALUNS

The Unadilla/Reyco/Inline W2DU-(6) and W2DU-(2) "Maxi" baluns handle 3.5 kW of power. Model W2DU-(6) is used for 160–6-meter applications, while the W2DU-(2) handles those in the 6-1-1/4-meter range. Pull-apart tensile strength is rated at more than 600 pounds. The baluns are adaptable to dipoles, inverted vees, quads, and yagi antennas. Both are contained in weatherproof housing and have built-in lightning arrestors.

For more information, contact Sandy Weegar at *Microwave Filter Co., Inc., 6743 Kinne Street, East Syracuse NY 13057; (800)-448-1666.* From New York, Canada, Hawaii, and Alaska, call collect at (315)-437-3953. Reader Service number 479.



"Maxi" baluns from Microwave Filter Co.

A VARIABLE-TEMPERATURE SOLDER SYSTEM BY UNGAR

A low-priced variable-temperature-controlled soldering system has been introduced by the Ungar Division of Eldon Industries, Inc. A rotary control on the base enables the user to vary the temperature in 50-degree increments from 400 to 800 degrees F. While the unit makes temperature-controlled soldering feasible for hobbyists and do-it-yourselfers, the Electronic Soldering System 9100 has features previously developed for the Electronic System 9000 for high-technology induction use.

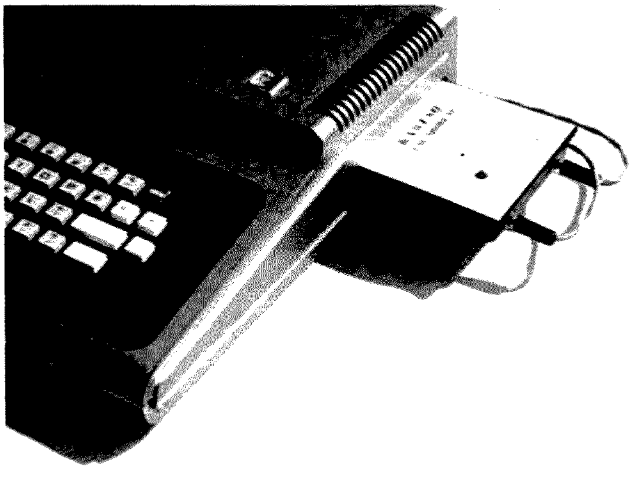
Ungar's recently introduced Thermo-Duric™ heating element, which combines an efficient heater and sensitive tip-temperature sensor, quickly recovers tip temperature after each solder joint. The smaller heating element also makes possible a thinner, cooler handle.

The iron holder can quickly be changed to the left or right side of the stand. Any of five Ungar soldering iron tips can be used. The system is electrically conductive from the tip to a grounded wall plug to prevent static electricity damage to microcircuits.

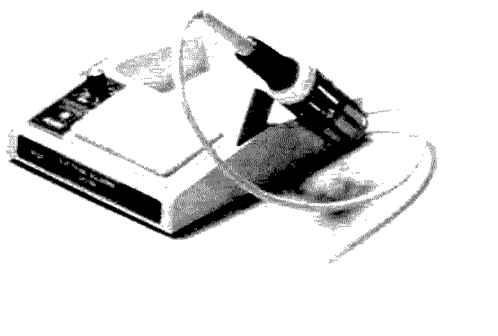
Further information is available from *Ungar, 100 W. Manville St., Compton CA 90220; (213)-774-5950.* In Canada: *Eldon Industries of Canada, Markham, Ontario L3R 1H5; (416)-495-9407.* Reader Service number 477.

THE FLESHER CORPORATION ROM-116 INTERFACE

Flesher Corporation has announced that it now exclusively distributes and sells the ROM-116. The ROM-116 interfaces to the Radio Shack TRS-80 models I, III, and IV with 16K minimum memory. Some of the features included are two serial ports, fourteen buffers, formatted or unformatted split-screen display, vertical status display, automatic CW ID, PTT control, selcal, error correction, and a text



The KA9FSQ CW modem from Mitronix.



The variable-temperature-control "Soldering System 9100" from Ungar.

editor. The interface also offers two independent callsign buffers, adjustable line length, all standard Baudot and ASCII baud rates (up to 1200 baud), and CW receiving and transmitting with full break-in.

Several software packages, including a mailbox program, are available.

For more information, contact *Flesher Corporation, PO Box 976, Topeka KS 66601; (800)-HAM-RTTY.* Reader Service number 476.

NEW HUSTLER ANTENNAS

With the renewed interest in 6-meter amateur operation, Hustler has added three new models to fulfill most antenna requirements.

The 6-MB3 3-element yagi features a 6-dB forward gain while maintaining a front-to-back ratio of 28 dB. Bandwidth is 2 MHz with an swr under 2:1. Resonance is centered at 50.1 MHz with an swr under 1.2:1.

Model G-3754 is an omnidirectional vertical endfed collinear antenna for fixed-station use, appropriate for repeater applications. Bandwidth is 1 MHz with an swr under 2:1. The antenna's gain is 3.4 dB developed from a .64-wavelength radiator. Vswr is 1.2:1 at resonance. The G-3754 and 6-MB3 are constructed of high-grade seamless aluminum tubing and stainless-steel hardware for durability and long life.

For mobile use, the new BBL-4554 base-loaded antenna features a 48-inch overall height and shunt-fed design for performance on any mode—FM, AM, or SSB. The antenna is supplied complete with stainless-steel impact spring, 3/4-inch hole mount, and 17 feet of RG-58/U coaxial cable with a PL-259 connector installed.

For further information, contact *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.*

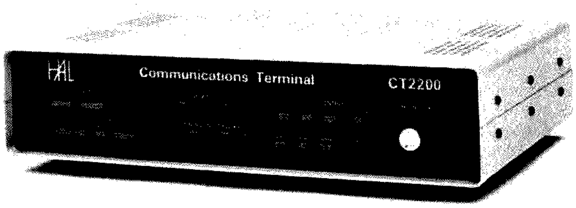
NEW 10M TRANSCEIVER FROM HEIL SOUND, LTD.

A very economical amateur-radio transceiver is now in production at Heil Sound, Ltd., in Marissa, Illinois. The 10-meter FM-10T is a completely wired and tested version of the kit that Heil introduced in 1979. The FM-10T is a complete transceiver capable of operating 29.60 to 29.70 MHz. Several added options are included in the FM-10T, such as the 6-kHz wideband FM filter, repeater offset, microphone, transmit-receive LED, and the 40-channel program switch and knob. The FM-10T is in a black and white aluminum housing.

For more information, contact *Heil Sound, Ltd, Heil Industrial Blvd., Marissa IL 62257.* Reader Service number 484.

The Flesher Corporation ROM-116.

Icom's IC-120 1.2-GHz transceiver.



The Hal Communications Corporation CT2200 communications terminal.

HT POWER AMPLIFIERS FROM MFJ

MFJ Enterprises now offers 430-MHz and 2-meter power amplifiers which are small enough to mount on your HT. The MFJ-2040 (for 144–148 MHz) will deliver from 7 to 20 Watts output with an input from 0.1 to 3 Watts. The MFJ-2045 (for 430–440 MHz) will produce 4 to 15 Watts for the same input. Transmit/receive switching is carrier operated. The die-cast aluminum body is 1-1/2 inches in diameter and 3-3/4 inches long, which makes these amplifiers small enough to fit between your antenna and HT. The amplifiers require 12 to 13.8 V dc at 50 mA for receive and 1 to 2 Amps for transmit.

For more information, contact *MFJ Enterprises, Box 494, Mississippi State MS 39762; (800)-647-1800.* Reader Service number 482.

ICOM'S NEW 1.2-GHZ FM MOBILE TRANSCEIVER

The IC-120 is a 1.2-gigahertz FM mobile transceiver covering 1260 to 1300 MHz. This unit is styled similarly and has features similar to the IC-25A/H series of 2-meter transceivers and has many common features. Duplex split is variable, but is initiated at 20 MHz when the unit is first turned on. Duplex up and down as well as scanning features are offered. Power output is 1 Watt. Icom is the first to offer hams a full-featured mobile transceiver for this mostly unused band.

For more information, contact *Icom America, 2112-116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

HAL OFFERS NEW CT2200 COMMUNICATIONS TERMINAL

The CT2200 is the successor to the CT2100 communications terminal. It offers all of the features of the CT2100 plus keyboard programming of all eight "brag-tape" messages and programmable selective call control of the printer output. The terminal also has a manual printer on/off control, non-volatile storage of HERE IS, "brag tape," and selective call codes, and new rear-panel connections for use with the ARQ1000. The CT2200 is a new product that replaces the previous CT2100, but an update kit (including a new front panel) is offered to upgrade the CT2100.

For more information, contact *Hal Communications Corp., PO Box 35, Urbana IL 61801; (217)-367-7373.* Reader Service number 480.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Let me take a wild guess. I will bet that many of you active on RTTY are still using some form of old, boat-anchor type of equipment. Right? I thought so. For just because this equipment is old does not mean it cannot still put out a fine signal on RTTY. With proper interfacing—such as we have covered here in months gone by—even a thirty-year-old transmitter can be connected to a modern RTTY terminal.

But just as there are changes which bring a new season, so have hams changed from power- and space-hungry tube equipment to the new state-of-the-art, solid-state, compact transceivers. Many of them feature a RTTY or FSK detent on their mode switch, but are they really usable? Promotional literature does little to point out those minute features which make operation on FSK a pleasure or a pain, but the average ham will turn them up in a few hours of on-the-air time.

I recall the flap which arose a number of years ago when a well-known company offered a transmitter which featured an FSK mode, ostensibly designed for radioteletype. However, entering that mode shifted the transmit frequency almost three kilohertz from the receive frequency, making it impossible to use the transmitter with its companion receiver in transceive mode on RTTY. It is because of such problems that modifications are made, and I solved that one and published the solution some years back.

Let me know what your experiences are with some of the newer HF equipment being sold which features a RTTY mode. I will try to pass along whatever information I get that I can verify on what's good, bad, or super in the way of equipment to put RTTY on the air. And if you are considering buying a new transceiver, watch here for whatever information we turn up which may influence your choice.

Speaking of your choices, the mail has been running heavy lately. Let's see what some of you have to say.

From St. Leonard, Maryland (quite a distance from me here in the Baltimore area), comes a letter from V. L. Thrasher KB3FS. V. L. writes that he has looked through all the catalogs he has in search of some 88-mH toroids mentioned here some months back, with no luck. He is using a Model 15 Teletype® with an ST-5 type demodulator and wants to build an oscilloscope display which will require the toroids.

Well, V. L., several years ago it was relatively easy to find a parts house that advertised the toroids in question. Usually surplus or removed from service in bundles of five, they most often originated with telephone company equipment. But as that source has modernized and thus obviated the need for toroids in tuned circuits, the supply of toroids has also dried up. I would first suggest searching

through catalogs of surplus jobbers, as I assume you have done. Coming up blank there, ask around at the local ham club or the like; often a pack-rat ham, such as I was in my younger days, will have two or three bunches of toroids stashed for a rainy day.

If all this fails to find any, I have found that the best place to find odd parts at the right price remains a hamfest, and this column should be published right around the time of the big Foundation for Amateur Radio hamfest which takes place in Gaithersburg, Maryland (a suburb of Washington DC), every fall. Check the tables there, and good luck.

As an aside to those of you in the sales end of this parts problem, don't forget the home-brewer. Even though a great bulk of hams purchase high-tech gear, a trend which this magazine has shown, building it yourself is far from dead! We need parts—resistors, capacitors, coils, and the like—besides the semiconductors that are available everywhere. Address that market and you may find that you are alone in the field, with plenty of takers.

Regards to Ron Hatton WA4BDY/DA2SR, who currently uses an APO box in New York for his mail. Ron is a computer buff who numbers himself among those waiting for a RTTY program. Also in that crowd is Ray Baumiller WB3HDZ, from Montgomery, Pennsylvania. What these fellows and many others are interested in is a program to place one of the easiest microprocessors ever devised, the Motorola 6800, on RTTY as a full-featured RTTY terminal. Such schemes are being used commercially, as with the excellent series of products being produced in Gaithersburg, home of the hamfest, by Microlog. By choosing the 6800 as their CPU, this fine company is able to produce a versatile RTTY terminal with all of those features the active ham requires.

Of course, as has been stated here before, many consider the 6800 and its family of related chips a dead series. But as Larry Antonuk WB9RRT/1, in Keene, New Hampshire, puts it, "Is the Model 28 dead? Of course not." He is another in the group that would like to see a program devised to transmit and receive RTTY which would not require buying the latest high-tech box.

Unfortunately, it would appear that such a program may well be too limited in appeal to publish here, no matter how vocal are those who desire it. Therefore, I shall be investigating other ways of disseminating the kernels of this program so that it can be used by those interested. At the same time, I will not bore those who are tired of reading about CPUs, RAM, ROM, etc., by continuing to discuss those topics in "RTTY Loop."

That said, I would like to add one thing. Nothing is cast in concrete. If there is a topic you would like to see covered in this column, and I have not covered it to your liking, write me and write the editors of *73*. Let your voice be heard! If enough of you want to read about this or that, I am sure the editors will give it the nod.

On a sadder note, I have received word that the Stark RTTY group in Massillon, Ohio, is dwindling. I am not sure of the origin of the dwindle but hope that the situation is only temporary. Through the years I have been involved with many clubs and organizations (not all of them amateur radio in nature) which go through such a period of ebb tide. Often they just fade away, and all the work and love put into them by the founding members is discarded as so much old rubbish. But sometimes, not often, but sometimes, a new spark is felt which rekindles the interest. Let's hope such a spark strikes in Ohio real soon. Keep me posted, folks.

Observant readers will note that the address at the top of the column has changed once again. I am now at the new QTH and shall do what I can to get on the air as quickly as time, finances, and the XYL allow. In the meantime, I plan some rather exciting editions of "RTTY Loop" in the months to come: a look at AMTOR for example—the new, but really not so new, technique of sending RTTY that is essentially error-free. And we'll also have feedback from my questions to you about on-the-air mailboxes, commercial equipment, and the other things that bug and cheer the amateur on RTTY. Stay with me, and let me know what you are doing!

DR. DIGITAL

Robert Swirsky AF2M
412 Arbuckle Avenue
Cedarhurst NY 11516

Good news! The FCC has lifted that silly identification restriction for RTTY. Since June 15, 1983, there is no longer any need to ID in CW or voice while running Baudot, ASCII, or AMTOR. If you are running some other digital code, you must ID in any one of the three "accepted" digital codes. Of course, you can still ID in voice or CW if you like that sort of thing.

A while back, John Edwards KI2U (you know him as Mr. Fun!) petitioned the FCC concerning this very issue. John correctly pointed out that the CW ID requirements were a major annoyance to RTTY operators; the CW often messed up the printout. Just as a courtesy, John sent a copy of the petition to the ARRL. He received a nasty reply saying his request was a foolish one and the FCC would "*never* in a million years" go for such a silly proposal. Well, ARRL? Don't tell me a million years have already elapsed.

I found it interesting that many amateurs are upset about the new identification rule. It seems that some feel the RTTY people will now take over amateur radio, transmitting in their "secret code" that only other RTTY operators can copy. I wonder if the AMers wanted the SSB people to identify in AM, or if the spark-gap people wanted the CW people to identify with a modulated spark-gap rig? Why is it that even the most minor rule changes must overcome considerable inertia before being accepted by the amateur community?

Cyclic Redundancy Checks

Last month, we discussed the Longitudinal Redundancy Check. While the LRC is certainly easy to implement, it isn't that *efficient*. There are many errors that it can't detect or correct. A better error-correcting scheme is called Cyclic Redundancy Check (CRC). It is more efficient that the LRC and can detect and correct a wider variety of errors. But there is a catch...

"There is no such thing as a free lunch," the adage goes. The CRC is a little bit more difficult to understand than the LRC and is harder to implement. Bear with the explanation. It might seem difficult at first.

The CRC involves representing a series of bits as the coefficients of a polynomial expression; let's call this expression the message function M(x). This message function is operated on by a generator function of a lower degree than M(x). Before the transmission of data, the message polynomial is operated on as shown in Fig. 1.

The generator polynomial is chosen according to certain criteria depending on amount of redundancy desired and the number of bits transmitted in each block. Also, multiplying the message polynomial M(x) by X^P will result in adding P zeroes in the least significant positions of M(x) without disturbing the higher-order bit positions. Division by the generator polynomial P(x) is done using modulo-2 arithmetic (no carries). Q(x) is the quotient, and the ratio R(x) over P(x) is, of course, the remainder. The result of this process yields a string of x bits which is appended to the data block and transmitted along with the message data. The transmitted message is the polynomial T(x).

On the receiving end, the message is operated on using the same generator polynomial as the transmitter. Fig. 2 shows the equation for this operation. If the remainder is anything other than zero, an error has occurred. The position of the errors can be represented by another polynomial, E(x), which would be of the same form as T(x) (the transmitted message). The relationships among all these polynomials can be seen in Fig. 3.

To recapitulate in simpler terms, the

$$M(x) = Cx^n + Cx^{n-1} + Cx^{n-2} + \ldots + Cx^0$$
$$M(x)x^P/P(x) = Q(x) + R(x)/P(x)$$
$$T(x) = M(x)x^P + R(x)$$

Fig. 1. Equations for the message polynomial, the generator operation, and the transmitted message.

CRC involves subjecting your data to a specific formula. The person receiving the data applies the same formula; if the remainder is non-zero, there was an error. By examining the value of the remainder, it is possible to detect a large number of errors. Cyclic codes are more efficient in detecting errors than any other method; less redundancy can find more errors.

Need Help With Math?

If it has been a while since high school and you are out of practice with mathematics, there are two books I strongly recommend. The first is *Realm of Algebra*, by Isaac Asimov, Fawcett Crest, New York, 1967. This concise 143-page book clearly describes arithmetic and algebra and demonstrates practical applications. If you just want to brush up on your algebra, this book is ideal.

Less succinct, but covering more topics, is the classic *Mathematics for the Millions*, W. W. Norton & Company, New York, 1983. First published in 1937 by Lancelot Hogban, this 648-page book is regarded as one of the best guides to mathematics for the layman. Despite its length, it is not prolix; this book is a complete course in mathematics starting at the very beginning and leading into advanced topics. In fact, given the comprehensiveness of this volume, it is remarkable that it is under 1000 pages. Both of these books are in paperback. If you feel limited because of an inadequate mastery of math, these books will prove most helpful.

Computer Slow Scan

Using the graphics capabilities that many microcomputers have combined with a reasonable amount of memory, microcomputer slow scan is feasible. Although few of the home computers have the proper graphics features for a full-resolution SSTV picture, reasonable results can be obtained by sacrificing grey levels. A commercial scan converter (e.g., Robot)

$$T(x)/P(x) = M(x)x^P + R(x)/P(x) = Q(x) + \text{Remainder}$$

Fig. 2. If remainder is not zero, an error has occurred.

$$T(x) + E(x)/P(x) = T(x)/P(x) + E(x)/P(x)$$

Fig. 3.

usually produces a picture that has 128 by 128 pixel resolution with 16 shades of grey. Many microcomputers can easily handle the 128 by 128 pixels but lack the grey-scale capabilities.

One of the earliest efforts with computer SSTV was by Dr. C. H. Galfo WB4JMD. The Galfo SSTV program, without *any* additional hardware, enables an Apple II owner to receive SSTV. Using a resolution of 128 by 128 with three grey levels, the program adds some random noise to the picture to give the illusion of an increased grey scale. While the pictures are very high contrast, they are quite acceptable. I have found *that* the smaller the monitor, the better the results; on a 5-inch TV, the pictures are very clear.

SSTV uses the following tones: 1200 Hz (sync), 1500 Hz (black), 1900 Hz (grey), and 2300 Hz (white). Of course, if the hardware is capable of handling more grey levels, additional tones between black and white will be decoded.

Dr. Galfo's program is able to decode SSTV with no additional hardware due to the characteristics of Apple's cassette interface. The program is an excellent example of software replacing hardware. Also integrated with the Galfo SSTV program is a routine to transmit SSTV. Characters and block graphics are entered using the keyboard, and the computer translates them into the appropriate SSTV tones which come out the cassette port.

Apple uses a zero-crossing detector in the circuit of the cassette port. Every time the audio waveform into the detector crosses the zero line, the detector changes its state; if it was a 1, it is now 0 (and vice versa). Since the Apple II uses memory-mapped I/O, the state of the cassette port can be determined by doing a read to the proper location. If the computer is programmed to count from one 0 to 1 transition of the cassette port to another, and if the amount of time it takes for the counting routine to increment is known, the frequency can be determined. This is the method that Dr. Galfo uses in his SSTV program; the same method has also been used in a number of programs that demodulate RTTY with an Apple and no additional hardware.

It should not be all that difficult to use other computers for SSTV. One micro that might be suitable is the Atari. Atari uses a custom microprocessor to control the graphics; this is separate from the main 6502 microprocessor. The graphics pro-

cessor is controlled by a special program called a display list. Further control over the graphics can be obtained by controlling the amount of Direct Memory Access (DMA) the chip gets during the horizontal-scanning interval. In the highest resolution graphics mode, with the DMA register set for 128 pixels across and the display list constructed for 128 lines vertically, the 128-by-128 resolution can be achieved without wasting any memory.

Because the graphics memory can be located anywhere in main memory and an interrupt can be generated during the vertical blanking interval, it is a simple matter to swap among a number of graphics memory pages every 60th of a second. Since the swap occurs during the vertical blanking interval, no flickering will occur. If four 128-by-128-bit pages are cycled on the screen, it can give the appearance of 6 grey levels.

The Atari's DMA requests from the graphics microprocessor leads to a problem: The computer can't time an event by counting clock cycles. Whenever a DMA request occurs, the microprocessor will halt briefly, causing timing disturbances. This would make it difficult to decode SSTV in software. One possible solution is to have a one-line tuning indicator on the screen while the computer is decoding. The DMA calls needed to display 1 line of character graphics would not interfere with the 6502 microprocessor as severely as a full-screen graphics display. The disturbances in timing that the DMA requests do incur can be accounted for.

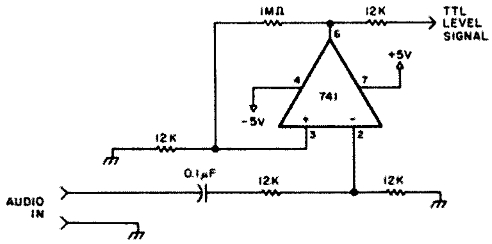


Fig.4. Zero-crossing detector.

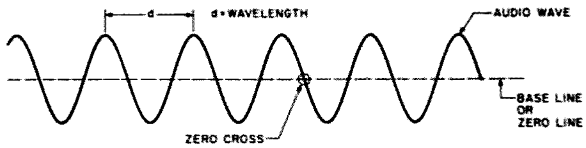

Fig.5.

The Atari cassette port, unlike Apple's, does not have a zero-crossing detector (it is incorporated within the 410 or 1010 recorder). A suitable circuit for a zero-crossing detector is in Fig. 4. This circuit will provide a TTL-level signal. Every time the audio signal crosses the base line (Fig. 5), the state, 0 or 1, will change.

Graphics Standards

It would be nice if one could exchange graphics over the air between computers. Since many computers have graphics, all that is needed is a standard. While protocols exist—such as NAPLPS (North American Presentation Level Protocol Syntax)—they are probably overkill for a radio amateur's needs. A simpler way, which can be made compatible with NAPLPS, would be to devise a special graphics character set that would contain symbols needed for amateur radio. The advantages of character-set graphics are numerous: Many computers can accommodate alternate character sets, standard ASCII can be used to transmit the data, any printer with programmable character sets can be used for hard copy, and it will keep graphics information compact.

I would appreciate any suggestions regarding a ham-radio graphics character set. My final decision as to what the character set contains will be in an upcoming column. It would be nice if such a character set became commonly used on amateur radio; just think, using the character-set symbols over RTTY, you'll be able to exchange schematic diagrams and flowcharts!

Keep those letters coming in! Remember: If you want a reply, please enclose an SASE.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

HAM SLANG

What do you think Mr. FUN! does when he goes looking for excitement? Well, one of the things he's likely to do is grab his brother, catch the Eastern air shuttle, and spend a day museum hopping in our nation's capital.

While my favorite spot is the National Air and Space Museum (with its OSCAR 1 exhibit), a close second is the recreation of the 1876 Centennial Exposition at the Science and Technology Museum. Last Saturday, as my brother and I were browsing through the impressive display of ladies' bustles, steam engines, and patent medicines, we stumbled upon a section of the museum we had never noticed before—an exhibit devoted to Samuel Morse (of Morse code fame). Among the objects on display were Morse's notebooks, his medals, and a very wide selection of telegraph keys, relays, and related equipment.

"Hey!" shouted my brother (WB2LWJ). "You know something?"

"What?" I replied.

"Everything else in this museum is straight out of a history book. But this exhibit looks like it came out of a modern ham shack."

"Jim, you're very astute," I noted. "You see, many hams regard 'state-of-the-art' technology as equipment that existed at the year of their birth. Most think that change is something to be feared. 'If it worked in the past it's good enough for today,' is the conventional wisdom."

"Is that why the ARRL intends to use CW nets in the event of nuclear disaster?" asked Jim.

"Yes," I answered, admiring my reflection on the surface of one particularly nifty bug.

"Isn't that sort of like the Polish government relying on its cavalry to defeat the invading German Panzer Corps?" he questioned.

"Museums can teach their visitors all sorts of things," was my response as we moved over to the display of hand-cranked printing presses.

Our topic this month is ham slang—you know—the buzzwords and jargon we use to scare newcomers away from our hobby. Next to CW, it's our best line of defense.

ELEMENT 1
MULTIPLE CHOICE

1) While there are many explanations for the origin of the term "ham," which of the following is the most commonly accepted?
   1) A telegrapher's term for a show-off
   2) A telegrapher's term for a poor operator
   3) A telegrapher's term for a good operator
   4) We were named after the "ham switches" found in most turn-of-the-century shacks

2) In the early days of our hobby, what was another common nickname for a radio amateur?
   1) Spark Jockey
   2) Plug
   3) Beefer
   4) Wirelessist

3) One hundred and sixty meters is often called:
   1) The top band
   2) The bottom band
   3) The DX band
   4) The quiet zone

4) You'll find the "graveyard":
   1) On 27 MHz
   2) On 2 meters
   3) In the AM broadcast band
   4) After standing near a microwave dish

5) Prior to 1976, what was meant by the term "Novice Gallon"?
   1) The supposed amount of perspiration generated by a prospective ham during the Novice theory test
   2) 100 Watts of input power
   3) 250 Watts of input power
   4) 75 Watts of input power

ELEMENT 2
MATCHING

Q signals were originally developed to help speed CW communication. Today, ham radio just wouldn't be ham radio without these confusing little buggers popping up during our daily "QSOs." Try and match the Q signal in Column A with its correct meaning in Column B.

A	B
1) QRG	A) I have nothing for you
2) ORH	B) Repeat your last message
3) QRI	C) It is my turn
4) QRK	D) I am busy
5) QRL	E) Increase your power
6) QRM	F) Your antenna is faulty
7) QRN	G) Send faster
8) QRO	H) I am calling you on
9) QRP	I) Your signal is fading
10) QRQ	J) I am ready
11) QRS	K) Stop sending
12) QRT	L) Your frequency varies
13) QRU	M) You are being called
14) QRV	N) I am acknowledging receipt
15) QRW	O) Decrease your power
16) QRX	P) Call me again
17) QRY	Q) Send messages
18) QRZ	R) Your signal is distorted
19) QSA	S) Send slowly
20) QSB	T) I am troubled by static
21) OSD	U) Your transmission is being interfered with
22) OSG	V) Your exact frequency is
23) QSK	W) The tone of your transmission is
24) QSL	X) Your intelligibility is
25) OSM	Y) Your strength is
	Z) Break your transmission

ELEMENT 3
SCRAMBLED WORDS

Unscramble these examples of ham slang:

NIEACMH	MINTERDO
QCHLESU	CAIND
YREKE	MCTAMSNART
PUPIEL	TEN
AXF	GIR
TFIHS	UADQ

THE ANSWERS

Element 1:

1—2 Then what's a "lid"? A bad, bad operator?

2—2 A plug, like a ham, was a poor operator.

3—1 Tops in wavelength; also known as the "gentleman's band."

4—3 That portion of the band (roughly between 1200 and 1400 kHz) where the FCC assigns low-powered broadcasters.

5—4 Using crystal control, of course.

Element 2:

SCORING

Element 1: Seven points for each correct answer.

Element 2: One point per match.

Element 3: Three points for each word unscrambled.

Where do you stand in the jargon jungle?

- 1-20 points—Think a Wouff Hong is a new Japanese HT.
- 21-40 points—Call CQ on repeaters.
- 41-60 points—Reside in a QTH, but think 10-codes are silly.
- 61-80 points—Five by nine.
- 81+ points—FB, OM!

REVIEW

READER COMMENTS: GORDON WEST TAPES

I read with pleasure the comments of Avery L. Jenkins WB8JLG, *73* Staff (page 120, *73*, July, 1983), regarding the code cassettes of Gordon (Gordo) West WB6NOA.

Gordon West's cassettes are truly a great advance. In addition to being in stereo compatible with mono, the cassettes are professionally recorded on C-90 high-quality cassettes. West's cassettes—unlike the ARRL code-practice cassettes—are generated by computer and sound *exactly* as the FCC exams sound. For some reason, the ARRL generates code at 16 wpm with spacing to slow it down, and at 13 wpm the sound does not sound similar to the FCC tests. I used the ARRL cassettes to get my speed up (I thought) to 13 wpm and promptly flunked the FCC 13-wpm code exam twice. Then I discovered the West cassettes, and in March, 1983, I passed the FCC 20-wpm code and written exams on the first attempt (I now have an Extra-class license).

Also, there are excellent West cassettes available for the theory part of the Novice, Technician, Advanced, and Extra written FCC exams. These are not designed to stand alone but, in my opinion, are excellent training aids. The West cassettes certainly worked for me and I am extremely grateful to Gordon West.

It should be pointed out that my only contact with Gordon West is as a customer (a very well-satisfied customer).

These cassettes are very useful to listen to in an automobile using the cassette stereo system. While learning the code, the trainee can merely listen—without writing the copy—to recognize the letters instantly. Of course, one must also learn to write copy while listening to prepare for the FCC code exams.

The FCC code exams are not random characters but are plain copy. If one is interested in passing the FCC code exams, working on plain copy is the proper study method to use.

Gordon West says on the cassettes, "There will be no surprises." I attest to the fact that this is certainly the case. Anyone preparing for an FCC exam, even those given by volunteer examiners, should contact Gordon West WB6NOA for the appropriate cassettes.

READER COMMENTS: THE AUTEK QF-1A

Concerning your recent review of the Autek QF-1A audio filter, I am writing you with my own review.

As a heavy (95 percent) CW operator, the QF-1A is for me a valuable tool in bringing a signal up out of the noise. For me, the best results are obtained by using the Aux Notch control to take out QRN and then peaking the CW note with narrow selectivity to keep down QRM. Extra bonus: With the filter's audio amplifier, the CW sidetone of my HW-101 comes through very loud. A quarter-turn of Aux Notch brings sidetone levels down nicely.

I have not had a chance to use the filter on SSB very much. It seems to do a nice job in making "trash audio" fairly intelligible. The peaking of mid-range audio seems to be the best bet.

Autek's suggestions of appropriate functions for different modes/conditions are of great help in discovering how to improve audio. Their condensed list of the above (given in the instructions) I copied onto some index cards and taped to the top of the unit for quick reference.

I saw the QF-1A for the first time about 3 years ago as an SWL. After a demonstration, I told myself I had to have one. When mine came in July, 1983, I tried it out first on an SWL communications receiver. SWL fans should note: The QF-1A is a very valuable tool for cleaning up faded, choppy, or interfered-with signals. SWLs should seriously consider the unit for making their hobby more enjoyable.

The Autek QF-1A beats any other unit (as far as I can determine) in function, performance, and price. It would make a nice addition to any ham/SWL station where cleaning up a bad received signal is a concern. (I believe that covers just about everyone.) I am pleased with my unit.

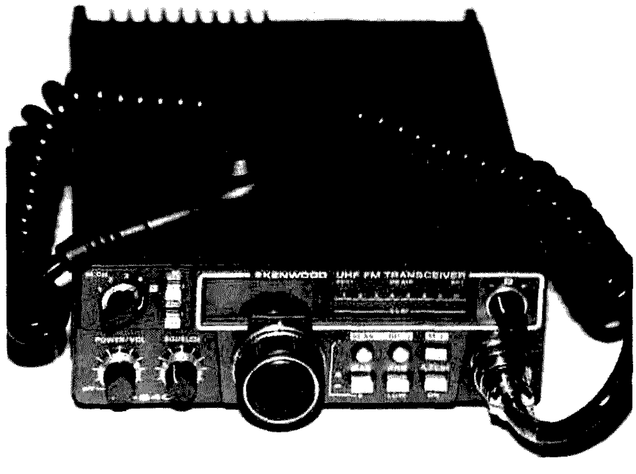
KENWOOD TR-8400

Those new, smaller, more-fuel-efficient cars really put the pressure on amateur manufacturers for new, smaller, more-space-efficient mobile rigs. (I often wonder what car dealers think when the first thing I do in their showroom is survey under the dash for space availability and ease of wiring in that new prospective car.) Well, if you're into 440-MHz FM, the folks at Kenwood have sure made life easier. The TR-8400 is downright tiny. Measuring just 2" high by 5-3/4" wide by 8" deep, the radio will easily fit into even the smallest car.



The Kenwood TR-8400.

But don't let the small size fool you. The 8400 is a microprocessor-controlled 10-Watt rig with memories, scanning, and all those niceties that state-of-the-art computer technology provides.

Features

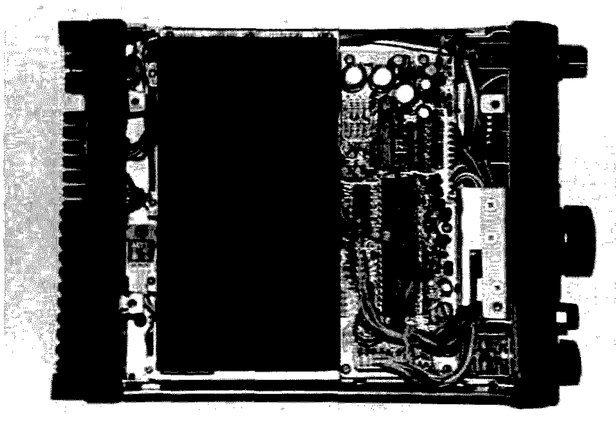
Two vfo's designated "A" and "B" step in 25-kHz increments, which is compatible with the US and Candian band plans. Five memory channels can be stored and recalled with either a five-position switch or with the scanning function. Memory 5 can be used for operation of repeaters with other than 5-MHz frequency splits. On this channel, the transmit and receive channels are memorized separately. Channels 1-4 as well as the vfo's are preset to provide a plus or minus 5-MHz split. In addition, simplex operation can be selected.

Two types of scanning are provided, memory scanning and band scanning. In the memory-scan mode, each of the five channels is scanned at a rate of 1 channel per second. Band scanning is at a much faster rate, described in the manual as 120 ms per channel (about a tenth of a second). This may seem fast, but when you are considering that the entire 10-MHz-wide band is being scanned, this rate is fine. Scanning the entire band takes only 50 seconds. If the squelch is opened by a signal, then scanning stops until the signal disappears, then scanning resumes from that frequency. If you want to listen further to that conversation, you must disable the scan function with the front-panel switch or by momentarily depressing the push-to-talk button on the mike.

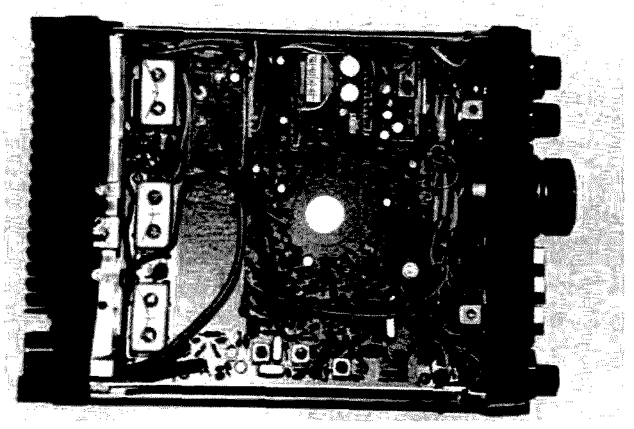
A tone switch is provided on the front panel to enable or disable either a subaudible tone or tone burst for repeaters that use this feature. It should be noted that Kenwood does not offer the actual tone module that is required, but the radio is compatible with standard products available from a number of sources; the manual even describes the installation procedure. Similarly, the TR-8400 includes an input for a separate autopatch touchtone™ pad.

The rf power output is 10 Watts with a lower power level of 1 Watt.

One of the best features of the 8400 for me was the microphone with up/down tuning buttons. Each push of the button ad-



Top view.



Bottom view.

vanced the tuning one step, which was indicated not only by the display changing, but also by a built-in beeper. Holding down the appropriate button doubles the scan rate and is indicated by a continuous tone.

Controls, Displays, Connections

Despite the small area available on the front panel, the controls are well laid out and are easy to use. As shown in the photo, the memory-channel-selection switch appears in the upper left corner with the memory-programming and memory-recall buttons to the immediate right. The memory-recall button switches between the vfo's and the memory channels. Below are the volume and squelch controls. The main tuning knob dominates the front panel and clicks off channels in 25-kHz steps. Each revolution moves you 1.25 MHz up or down so you can move quite rapidly between band edges. When you reach the edge, the microprocessor automatically starts you at the other end of the band. With a little forethought, you quickly start to think of the band as a circle. Any frequency can be reached by tuning up or down once you know the shortest route.

To the right of the main tuning knob is a cluster of six buttons in two rows. The top row controls scanning. The SCAN and HOLD buttons start and stop the scan function, and the M.S. (Memory Scan) selects either vfo scanning or memory scanning as described earlier. On the bottom row is the vfo-select button ("A" or "B"). An LED lights to indicate when vfo "B" has been selected. A high/low power switch and the tone activation switch are also included. Above the microphone connection is a three-position rotary switch for selecting the transmit frequency shift, plus or minus, or simplex operation. A five-digit red LED numeric readout indicates frequency down to the whole kilohertz (example: 449.275 is shown as 9.275).

An LED light bar shows both rf power output and relative received signal strength. Individual LEDs indicate busy channels, transit mode, and repeater operations.

Rear-panel connections are provided for an external speaker, a tone-pad input, dc power, and an antenna.

On-the-Air Operation

I'm sure that in the design of any radio there are certain trade-offs to be considered, especially when so much is packed into such a small space. However, if there were trade-offs here, they did not affect the performance of the radio. Even the receiver-audio output was in abundance and the speaker could be driven loudly and still produce a crisp sound. Transmitted-audio reports were also excellent, and no operational problems of any sort were experienced with the radio. By far my favorite feature was the microphone with its up and down frequency buttons. Talk about being addicted to video games! After a few hours with readouts flashing and beeper beeping, I could land on a channel at will practically with my eyes closed.

I did manage to come up with a few ideas for possible future refinements. I am personally a bit partial to the use of type N antenna connectors at these frequencies and the one provided was a so-called UHF type. The digital readout is a bit difficult to see in direct sunlight, as are many others. The readout does not indicate the transmit frequency, but only the received frequency, even in the transmit mode.

Manual

The manual is very understandable with numerous pictorial diagrams. All functions and features are fully described. A block diagram and schematic are included, but there is little information regarding the circuitry. A separate service manual is available which contains this information.

Summary

The TR-8400 is both enjoyable and reliable. The features are well thought out to provide plenty of utility without a lot of complexity. This is an important consideration when selecting any mobile radio.

THE SUPER SANTECS

A short time ago, while discussing the no-code license proposal on a local repeater, a user with views different than mine accused me of not even knowing what time it was. He had failed to reckon with the fact that I was using a Santec ST-440/uP. By merely throwing a front-panel switch on the radio, I was able to hold my own in the conversation, as the Santec instantly displayed the correct time.

In addition to their timekeeping abilities, the Santec ST-/uP handie-talkies are lightweight, relatively compact radios with a number of innovative features. The 144- and 440-MHz versions have been in production for some time. The importer, Encomm, Inc., introduced the ST-220/uP, the world's first scanning 220-MHz handie-talkie, at the 1983 Dayton Hamvention.

Several particularly good features of these radios involve their receive sections. The radios wake up on whatever receive frequency is stored in the first memory. Each radio remembers ten receive channels, complete with transmit offsets. Santec says the tenth memory, which also serves as the upper scan limit when scanning a band, won't retain a transmit offset after the radio is switched off, but in fact it will retain simplex or negative split (transmit 600 kHz below the receive frequency), while the first nine will retain simplex, positive, and negative splits and non-standard offsets. Non-standard splits are handled by the ability to program memory channels 2-9 to receive on a designated frequency and transmit on the frequency stored in the first memory. In memory mode, the stored offset overrides the front-panel offset switches, so you know that when you select a memory channel, you are still ready to go on channel without checking switch settings.

In the squelched receive condition, if no signal has been received for about 90 seconds, the radios go into an idle mode. Current drain decreases to about 3 mA. Every 1.5 seconds, the radios sample the receive frequency for about 250 ms. Absent a signal, the idle mode continues. Pressing the PTT bar or receiving a signal during the sampling period restores the receiver to normal. Over time, this feature results in an average receive drain (in the idle mode) of 8-10 mA, which is comparable to many non-synthesized radios.

The receivers also feature an S-curve detector, which senses discriminator output voltage. When scanning, this feature causes scanning to stop whenever the discriminator voltage goes to zero, which means right on channel instead of 5 kHz high or low. The more usual squelch detector stops scanning as soon as enough signal is received to open the squelch, which may or may not happen exactly at the desired frequency. Also, the S-curve detector makes it possible to scan with the radio unsquelched, a useful feature for detecting weak signals.

On the ST-144 and the ST-220, the scanning interval can be set anywhere between 5 and 100 kHz, in 5-kHz increments. On the ST-440, the choice of intervals is 25, 50, 75, or 100 kHz. All offer four scanning modes: *Scan*, in which the radio stops for a short interval on each received signal and then automatically restarts; *Search*, in which scan must be restarted manually after stopping on a busy channel; *Open*, in which scan stops on the first vacant channel and requires manual restarting; and *Manual*, in which scan moves one interval up or down at the press of a keyboard button or runs continuously if the button is held for about 1.5 seconds. All this applies whether the scan is of an entire band, a designated portion of a band, or the ten memory channels. Scanning the ten memories in the Scan mode activates a priority feature; channel 1 is scanned first after each stop for a received signal on any other channel.

The receivers are quite sensitive, as the receiver specifications in Table I demonstrate. 12-dB SINAD occurs between 0.23 and 0.31 uV input, depending on the radio. The receiver sensitivity measurements were made on a Motorola R2001 communications system analyzer, courtesy of Eastern Communications Ltd., of Long Island City, New York. None of the radios exhibits any receive birdies, although the ST-144 and ST-440 each had one initially. See the comments on Santec service at the end of the article.

Transmitter-power output and current consumption are also shown in Table I. The medium- and low-power levels are fully adjustable; I set mine for approximate 6-dB steps near the band centers, 146, 223.5, and 445 MHz, giving one-fourth and one-sixteenth of full power. As Table I demonstrates, output at the medium-power setting tends to increase somewhat with frequency.

All three radios are powered by a battery of 8 AA nickel-cadmium cells rated at 500 mAh. A three-pin socket wired to the battery mates with a plug inside the radio. A fifteen-hour wall charger is supplied with the radio and plugs into its underside; a small PC-board external charge adapter is an available accessory which accepts the charger plug and the battery socket, allowing a second battery to be charged outside the radio. I found another use for the charge adapter, described later. A 5-hour rapid charger/power supply is also available.

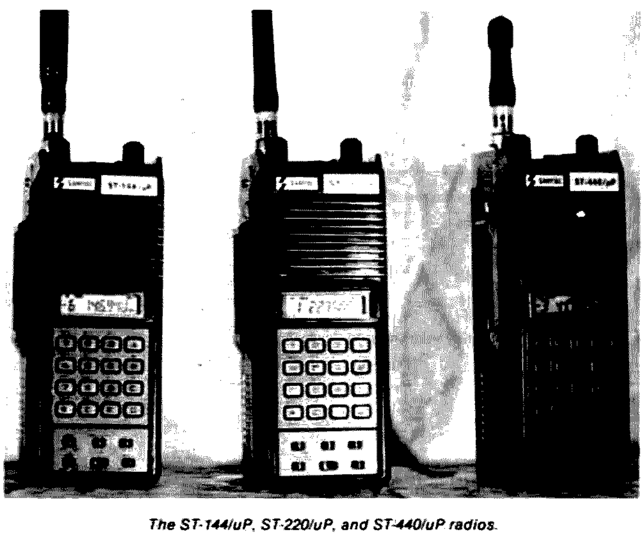
The radios all have the 24-hour clock feature that gave me such a ready retort on the repeater and an LCD frequency display with a night viewing light. The latter contains quite a wealth of information. First, all six digits of the receive or transmit frequency in use appear on the screen instead of the more typical 4 digits. (Frequency entry on the keyboard is the usual 4-digit process, e.g., 6125 for 146.125 or 446.125 MHz, except that trailing zeros needn't be entered, so 4 gets you 144.000, 224.000, or 444.000 MHz, depending on the radio). The display also shows: channel number (if you are on a memory channel) scan mode, and transmit offset as +, −, or 1 (for "transmit on the frequency in memory 1"). In memory mode, the offset programmed for each channel is displayed on the screen; in normal mode, the screen displays the offset for which the front-panel switches are set. There's a great deal of information in a small space.

The ST-144 receives from 142.000 to 149.995 MHz and transmits in all but the highest Megahertz. The ST-220 transmits and receives from 220.000 to 224.995 MHz, and the ST-440 transmits and receives from 440.000 to 449.975 MHz.

Negative comments? Only that the clock feature disables the memory mode. That is, if you are on a channel in memory, and you switch to the time display, when you return to the frequency display, you will be on the same receive frequency, but your transmit frequency will suddenly have become dependent on where your front-panel offset switches are set. Worse, every so often the switch into time display puts you back on the frequency in the first memory (as though you had turned the radio off and on again). This is rare, but it's mildly annoying when it happens.

Service on Santec radios is excellent. My ST-144 and ST-440 each had a single moderately strong receive birdie. Encomm responded to my telephone calls and asked me to send the radios back for repair. In each case, I received a postcard confirming receipt almost at once, and I had the radio back in seven days, with a work sheet showing what had been done to it. The Encomm warranty covers everything for 90 days and covers all semiconductors (excluding the output transistor) for two years; the replacement semiconductor is free, and there is a maximum labor charge of one hour at current shop rates.

I could go on to describe the installation of a memory back-up battery, a subminiature relay to disable the Santec's in-



The ST-144/uP, ST-220/uP, and ST-440/uP radios.

	ST-144/uP				ST-220/uP				ST-440/uP			
	144.0 MHz		147.5 MHz		222.0 MHz		224.5 MHz		441.0 MHz		449.0 MHz

MFJ'S ECONO TUNER

In the era of media hype—when every new rig has more memories, knobs, and LEDs—it is refreshing to find a plain vanilla product. The MFJ-900, dubbed the "Econo Tuner," fits that description.

MFJ produced the Econo Tuner to fill out the low end of its line of tuners, which range up to 2-kW capability with built-in swr meter. The 900 doesn't have a meter and is restricted to a maximum of 200 W. It does, generally speaking, match your antenna to your transmitter, which is the point of these gadgets anyway.

The only controls on the 900 are the transmitter, antenna, and inductance knobs. Tune-up is simple: Load your transmitter into a dummy load, tune it up, then switch to the tuner. With the receiver on, switch the coil knob until you find the point at which signals are their loudest, then start transmitting and play with the other two controls until your swr drops to an acceptable level. Of course, transmitter and antenna controls are interactive, which can make tuning up similar to flying a helicopter for the first time, but that is a condition inherent to antenna tuners.

The inductance control is a 12-position switch connected to taps on a coil. This technique has two advantages over the use of a rolling coil. The taps allow rapid access to the coil's extremes (for when you go from 10 meters to 80 meters) and it is a cheaper method to provide a range of inductances. A roller coil forces you to rotate the tap through the entire coil to get from one end to the other.

The coil and two variable capacitors are arranged in the classic T-circuit matching network. The coil taps are evenly spaced until they reach the high end of the coil. The last two taps are spread out, to give more even control of short antennas.

Two Flavors

The 900 comes in two flavors: with a coax connector and without. The latter is most useful for mobile or portable operations or when you are stuck in an apartment with an unforgiving landlord and your antenna doubles as bedsprings. Without the PL-259 connector, you need make only two rear-pannel connections to get the Econo Tuner operational. The antenna goes to one post and a good ground goes to the other.

The good ground is a necessity, regardless of the better radiation it offers. If too much rf is allowed to float around in the tuner, the signal may arc across the plates of the capacitors—which is precisely what happened in my shack the first time I hooked up the 900.

Previous to that, I had been using a tuner with a much greater power-handling capability (although I was running low power) and this tuner passed off the loose rf without arcing. But the zapping of the Econo Tuner was a needed indication of the poor state of my ground. The sturdily-built Econo Tuner suffered this indignity without damage and performed as advertised once I had rearranged my ground.

I found that the tuner is adaptable to a variety of operating environments. It has been used on three antennas, from a random-wire to a closely-cut multiband dipole, and I have inevitably been able to find the sweet spot on my swr meter.

One of the advantages of this tuner is its small size. It measures a scant 6 × 2½ × 5¼ inches—appropriate for a limited-space shack such as mine. The case is beige with wood-grain sides, and the terminals project less than an inch from the rear panel. Although I used it at my QTH, I can easily see the MFJ-900 on the move. If you intend to stow your rig in a backpack for a little backcountry hilltopping, I would think the 900 would be your tuner of choice.

It also comes with MFJ's unusual 12-month warranty. The 12 months is not by itself of interest, but MFJ does not void the warranty for fix-it-yourselfers. If your Econo Tuner stops working and you want to dig in and repair it yourself, you may do so with MFJ's blessing. And you can take advantage of the company's technical hotline if you find yourself in too deep.

The MFJ-900 sells for $49.95. For more information, contact *MFJ Enterprises, Inc., 921A Louisville Road, Starkville MS 39759.* Reader Service number 486.

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

FCC

Referring to the docket which eliminated logging requirements (PR Docket No. 82-726), the *Federal Register* published the following correction for Section 97.85(g)(4).

Erratum

In the Matter of Elimination of Logging Requirements in the Amateur Radio Service; PR Docket No. 82-726.

Released: June 20, 1983.

On June 8, 1983 (FCC 83-249), the Commission released a Report and Order in the above captioned proceeding. This document corrects certain typographical errors in the Appendix to that Report and Order published June 9, 1983, at 48 FR 26606. Section 97.85(g)(4) is corrected to read: "(4) The maximum transmitter output power which occurs during operation;".

GHOST FIGHTERS' CONSUMER GUIDE TO SATELLITE TELEVISION

Contrary to popular belief, satellite television isn't just another flash-in-the-pan fad. True, the excitement that accompanied the early days of the industry has diminished, but so have the entrance requirements. Prices are still declining, not only for antennas and receivers, but also for information. *Ghost Fighters' Consumer Guide to Satellite Television* is a good example of this trend towards economy. It provides 76 pages of information for $8.95, a far cry from the $25 price tag that many early TVRO books sported.

The Ghost Fighters manual is meant to bring you up to speed quickly on just what satellite television is and how you as a consumer can make a wise buying decision. For schematics or detailed technical data, choose another source (perhaps back issues of *73*), since this book stresses TVRO at its module rather than component level. With just a few exceptions, references to specific brands or manufacturers are avoided. Yet the book is surprisingly up to date, mentioning innovations that are in keeping with its 1983 publication date.

Most of the guide is devoted to the fundamentals of operation behind each link in a satellite receiving system. Given the author's background in antenna design, it isn't surprising that antenna selection receives heavy treatment. Other topics include the future of satellite television (including direct broadcasting) and the whys and wherefores behind three-foot dishes. Rounding out the book is an appendix that includes a listing of the 4-GHz television satellites as of early 1983 and a comprehensive glossary.

This consumer guide carries a home-brew appearance, yet features sound, conservative advice. It doesn't tell you what to buy as much as it tells you what not to buy. For all but the most novice madder, it will probably be old hat. But if you are starting out, the advice that this book offers could make the difference between buying a marginal system and a quality one.

For more information, contact the author, *James Anderson, Route 2, Box 136-B, Stevensville MT 59870.* Reader Service number 487.

LETTERS

TEENAGE JEWELS

Why do kids lose interest in ham radio here and not in Japan? So queried many of your editorials. Of course they lose interest, even after acquiring a license... unless we *involve* them. Kids need, more than anything, to be needed... to be acknowledged as creative, contributing human beings.

So, in Santa Cruz, California, we have a growing mob of teenagers wading into every facet of the ham-radio diamond, including through "each one teach one" classes. Our radio club has elected a teenager to take over prexy duties next year, which helps entice more young people to our meetings, and we make a point of inviting them and extending helping hands to them. When young Novices are introduced, the club enthusiastically applauds them.

We have bestowed used but usable radio stations upon two local junior high schools, assembled antennas, nurtured the responsive kids, etc. Now Del Mar Junior High is gradually focusing their whole curriculum around ham radio, school computers, and "Planetary Citizenship." A social studies teacher offers credit for study of the countries contacted through QSOs. English teachers help the kids write letters along with QSLing, and there is now a science elective for which the Novice and/or General exam is the final exam.

Kids mastering these demanding skills are rewarded by free sailing lessons and cruises on a sloop dedicated to world friendship by ham radio which cruises into foreign ports everywhere on behalf of everyone. On board, ham radio gives fun and games, stimulating ever more intense skill-mastering. For instance: You can play a lot of games with code. No one gets breakfast without asking for it in CW. (As we near Mexico, you have to ask for *huevos* in code instead of "eggs," of course.) You can stay stranded atop the mast all day unless you know how to ask in code to be cranked down. But the most motivating device is to start telling jokes about the CW laggard in code. He/she can't stand hearing others snicker mysteriously about him, so he gets code-wiser faster!

When we sail into different ports, we always get invited into schools. Our kids interview students and tape-record their ideas about whatever they are doing and plan to do about making the world work better. (We don't pretend to be gurus, knowing that real education asks more questions than are answered.)

As the word gets out and more kids realize that electronic communications via radio and computers empower them to climb right out on the cutting edge of the culture regardless of their age and rank, well... move over world, here they come!

Young people are just as hungry as ever to "put their highest powers to their highest use." Most of all, having generous, supportive older hams reach out to them encourages them to discipline themselves for skill-mastery. Then, having a school radio station or access to member stations keeps them at fever pitch.

If every ham club in this fractionating world were to sponsor a school club and see the kids through, and then turn over real responsibilities to them, such as sending traffic, field day, emergency services, etc., our ranks would solidify with youthful talent. I feel one of the reasons western culture is limping along is because we have not set a suitable stage for the creative energies of two or three whole generations. Helping our kids NOW to acquire these skills helps them to play in a major league of the World Game after their minor-league encounters with Pac-Man. I mean this letter to be a challenge!

Mary Duffield WA6KFA
Santa Cruz CA

Mary, the program sounds great, even if you answered a question I've never asked... about why kids lose interest in amateur radio. I've never known kids to lose the interest—only to not be exposed to it. Once it takes, it usually takes for life. You're exposing kids to the virulent virus of amateur radio and that's what we need. I'd sure like to see more clubs tackling local high schools and exposing the students to the best thing that can happen to them: ham radio.—Wayne.

KEEP STANDARDS HIGH

I feel that your editorial is right on the money when you talk about people with no knowledge of radio practice. But, there always were a few individuals that knew *nothing* about ham radio and were General-class licensees.

In the early 1960s, a lot of hams thought that the Technicians were mostly licensed by "friends" giving the test and "helping" them pass. There *was a* radio club that would *give* (literally) each new member the Technician exam; naturally, a knowledge of code or theory was *not* required. This went on until the FCC cut out the mail-order Techs.

I knew General-class operators that didn't know how to hook up a power amplifier to their rig without blowing out the receiver! Another General took the test *thirteen* times, each time memorizing a different part of the test.

The Bash material: Unless the FCC is composed of total morons, they have probably changed the code test twenty times since the Bash tapes reared their ugly heads. It is so easy for the FCC to make a different test for each examination date; they just use one of those computer Morse generators to type out the five-minute QSO. Having taken both the General and Advanced tests two and three weeks ago, I feel that the FCC theory test cannot be passed by memorizing. The only book that I used was a plain O & A and some of the ARRL publications to bone up on some of the rules and regulations. In all fairness, I have to admit that I also hold a commercial radiotelephone license and have been employed in the electronics industry. My amateur days go back over twenty years, being originally licensed in 1960.

Having passed both the General and Advanced tests, I feel that the best way to pass any amateur test is to have a solid radio knowledge. With all the money they are willing to spend on the Bash materials, they could buy some parts at their local electronics store and get "hands-on" experience using diodes, resistors, LEDs, and other devices. Basic parts are cheaper than ever, and there are many breadboarding kits for experimenters. I "mastered" the code with a $150 receiver (new) and several legal pads and about two months of one hour each day. With the $150 and the $50 worth of parts, one can have three things: a lot of fun, knowledge, and a ham ticket. They can keep the receiver as a gift for a job "well done." I feel this old-fashioned way builds amateur radio *operators*, not appliance users or high-powered CBers.

Let's keep ham radio standards high and attract the type of people that this hobby deserves.

Bobby J. Levow WB2MQK
Flushing NY

SOUTHWEST SNOBS?

First of all, I'd like to commend you on your efforts to further the cause of amateur radio through the pages of *73*.

I am the recipient of a few back issues from a friend who, like myself, is not a ham—which brings me to the root of my problem.

I want very much to be a ham, but I cannot find anyone in this area to give me some assistance with learning some of the things that are required to obtain a license. I've talked with several hams in the area; I also wrote to the League, only to receive the name of a gentleman who is no longer able to be an Elmer. I've even gone so far as to get on 2 meters illegally to find some help. I talked with WB5MLZ and told him eyeball to eyeball what was going on; after several inquiries, I could obtain no adequate help. But I did get chewed out for being on the air, so I promptly got off. What's wrong with the hams in the Albuquerque area? Are they totally ignorant of the many-faceted purpose of amateur radio? Are they only interested in making DX contacts in the HF region to faraway places? What about their own community?

I have some knowledge of electronics; I've been a technician for over 7 years. I also have a copy of a publication from the illustrious Mr. Bash, but who learns anything that way? (It's not mine; I was told by another ham to study it!) I've just recently gotten an Icom 2AT HT and an Icom 22S (which doesn't work yet) and I'd like to be able to use them legally.

There are supposedly two radio clubs in the Albuquerque area. One is the Albuquerque Radio Caravan Club, an erstwhile group whose claims to fame are the 147.060 repeater on Sandia Peak and the fact that they sponsor the amateur station at the VA hospital. The other group is the Upper Rio Grande Valley VHF Society which sponsors repeaters on 146.64 and 146.97 (They are lovingly referred to on the .06 machine as the Upper Rio Grande Valley Snob Society.) From all that I've heard while monitoring all three of these repeaters and others around here, it seems that the pet name applies to most of the hams in the area.

I have an extreme interest in becoming a ham and will work hard to do it soon, even if it means having to go to Denver for the test. I am also interested in meeting new friends, sharing ideas, and being the best ham I can, and I won't hesitate to help someone else become a ham if he's interested. I wouldn't want anyone to receive the reception that I got.

I do agree with you, Mr. Green, that amateur radio does need new blood and I'm all for the individual radio clubs handling licensing (but let's do it honestly—no $100 favors). But I disagree on dropping the code requirement. To do that would, in my opinion, open the doors to some pretty poor operators on the bands. We've got to have something to separate the wheat from the chaff. I do agree on lowering the code speed for the General license to 10 wpm and raising the Tech qualifications to 7 wpm. I myself would like to get up to 20-25 wpm before I get my General.

I also have en interest in computers and their relationship to ham radio, and I'm also an avid builder of many projects. By the way, my wife is also interested in becoming a ham.

Anyway, the whole point of my dissertation to you is that I need some help and can't find any willing people to give it.

Maybe I won't make many friends in the Albuquerque area by this letter, but maybe it will scare some serious hams out of the woodwork around here. At any rate, I'll monitor the HF bands on my general-coverage receiver and VHF on the HT until someone cares enough to give me a call. My number is (505)-881-2166.

Keep up the fantastic work, Wayne.

Leo Francis Fearon II
2933 San Mateo NE
Albuquerque NM 87110

Getting to the license, I really don't understand what the big deal is. If you get our code tapes, you'll learn the code just as have a hundred thousand other hams. If you get our Novice Study Guide, you'll learn enough theory to pass the written exam. So what do you need more than that? You might want to trade in your HT for a low-band rig since it's likely that your welcome on two meters in Albuquerque may be less than enthusiastic. One thing you should understand about repeater groups: The chaps who were open and friendly and talked with anyone were years ago pushed off the repeaters and are, for the most part, a dead species. They were replaced by a surprisingly small contingent of endless talkers who talk only to each other and tune a deaf ear to casual visitors to the repeater or to newcomers. A recent survey of New England repeaters showed that of the 437 known repeaters in the area, only eight are active—and they are domineered by seventeen hams. The other 26,000 licensed New England hams account for less than 1% of the repeater use. But even in the heyday of repeaters, when there were thousands of users, unlicensed visitors were not appreciated, no matter how good the intentions. "You say your house is on fire and you and the family are trapped on the third floor? Well, that's okay, but I missed your call. Please identify yourself. You know it's illegal to use a ham rig without a license."—Wayne.

95 DAYS TO CHRISTMAS

The 1982 Christmas Mail Call was the most successful ever. The staff of Armed Forces Mail Call expresses its appreciation to those who sent Christmas mail for distribution to the young men and women of our armed forces, both across the US and around the world. American Legion Auxiliary #49, Orange, Texas, was the leading group taking part, and Maudie Hensley, a member of that group, was the top individual participant. (Wilkins School in Amherst ranked number one in New Hampshire, Wayne!)

For eight years, Mail Call has received Christmas cards filled with newsy and friendly letters from individuals and groups all over the country. These Christmas greetings are then separated into some one hundred different bundles and sent by first-class air mail to various facilities of the Department of Defense (hospitals, chaplains, individual units, etc.), of

the Army, Navy, Marines, Air Force, to remote Coast Guard stations, and to Armed Services YMCAs, USOs, servicemen's centers, etc.

One letter we received, read: "The members of the -th Maint. Co. would like to express their gratitude for all the mail received under the Christmas Mail Call program. Many of our young soldiers received very little mail during the past holiday season. They were very pleased to go to the mailroom and find...mail from across the United States."

The 9th Annual Christmas Mail Call is now underway. This is an ideal project for individuals as well as families and groups and is an exceptional opportunity for letting our young military people know that we have not forgotten them, that we are thinking of them—especially at Christmas when many will not be able to be with their families but will be on duty at bases and posts across the US and around the world. (Mail was sent last year to the Marines in Lebanon as well as to the US peace-keeping forces in the Sinai.)

For information on how you, your family, or your organization may have a part in this unique program, please send a self-addressed, stamped envelope (business-size, if possible) to: Armed Forces Mail Call, Box Q, Holloman Air Force Base NM 88330 (and mention that you read about Mail Call in *73*). Thank you!

Lee Spencer
Holloman AFB NM

SURGE PROTECTION

Several letters and calls have been received from hams who have had trouble finding surge protectors in their local electrical supply houses. My article in the February issue of *73* describes these devices; however, not wanting to endorse any manufacturer, I did not mention any trade names. For those who may have trouble finding one locally, here are some catalog numbers:

- Square D Company—J 9200-10 Secondary Surge Protector.
- General Electric Company—TLP-175 Lightning Protector.
- Delta Company—LA-302 Lightning Arrestor.

With these numbers, one should be able to locate one in any of the larger cities.

Robert R. McKay N8ADA
Dayton OH

HISTORIC THROWBACK?

After reading your last editorial (July, 1983), I really hope that the status-quo code proponents are not winning. I have been watching the emergence of the no-code license with considerable interest over the years and feel that it is long overdue—but then, I felt that way when I got my license 20 years ago. Even back then the rationale for why an aspirant must demonstrate a manual skill at one archaic form of communications never made much sense. After all, one did not have to demonstrate the ability to use proper grammar to be able to use phone, take a typing test for teletype, or even a screen test to use television. Code always seemed to me to be a throwback in history—"I/we had to suffer through it, and so do you." Somehow, that mentality has miraculously been allowed to survive. I deeply feel this stone-age philosophy is *the* tragedy for ham radio.

Speaking personally—which is hard not to do on such an emotional subject—I'll list my personal observations and those of some people close to me who are not hams. To me, ham radio has probably been one of the strongest driving influences in my life. I can trace practically every major thing I have done back to it in some way.

I got my first license as a teenager in junior high school. A Technician license—to me there was no greater gateway to the exploration of the world of electronics than that license. From the start, I was fascinated by UHF and microwaves, so the lack of HF privileges has never meant much to me—at least with the Extra code-speed test. This has been true for all these years, so that first license I earned at the tender age of 14 is still the one I hold now, although I since have earned commercial-class radiotelephone licenses. I remember that ham license as my passport to learning in high school. While others were busy with sports, I was designing UHF transverters and dreaming of college.

I went to college and have never really left. I earned several undergraduate and graduate degrees in the hard and social sciences and medicine and am now in my third year of dental school. I sometimes wonder what I would have done if I'd not had ham radio as an outlet to explore science as a younger person. In the meantime, between schooling, I've worked as an engineer for a large university, designing microwave meteorological sounding devices, as an archeologist in Central America, and as a scientist at a medical school—to name a few jobs.

I've also been a day laborer more times than I can remember, always supporting myself by the sweat of my brow. And somehow, I've managed to travel the world.

The point of all of this is that I have had a chance to meet a great cross section of people from varied and diffuse backgrounds. Whenever the subject of ham radio is brought up, it nevers fails to excite an interest. When CB was big, everyone thought the two were the same. I was always explaining the difference, and with that difference, the excitement I felt about ham radio. Now, with few exceptions, these were interesting, intelligent, mature people, people that would be a charming asset to any organization. I see in them all the ability to bring to a group an enlivening vitality that few could not help but feel would make a positive contribution to any field—especially ham radio. I have never understood why, to be a real ham, you must be interested only in ham radio. So much better is the ham with a broad background who can bring these outside interests into ham radio.

But time and again, after detailing the positive aspects of my hobby, they would ask about the license requirements, and time and again the code was the turn-off. I never ran into anyone objecting to the technical exam; they could understand its need and felt sure they could master that aspect of the license. But they always asked me "why do I have to learn the Morse code?" I couldn't and still can't answer. Another asset is lost.

Others who are still determined to experiment with radio, I steer to FCC Part 5 on Class A CB. It is possible to do plenty of experimenting and radioing outside hamdom—but what a loss to our hobby!

I strongly feel that unless we can get people into ham radio at a level that is less than "perfection" and can grow within the hobby, that we will witness the decline and eventual death of ham radio before too long. There are too many people interested in our frequency bands and too many other outlets for young, probing scientific minds.

It is infuriating how time and time again that initial spark that could grow into a valuable addition to ham radio is squashed by that infernal code. Over and over, they have told me "I have better things to do with my time than learn Morse code."

Sure, we have a simple entry-level license: Novice class, and it is a joke. They are allocated slivers of bandwidths in high-QRM bands and forced to read code. Code! When the whole world speaks through computers, over satellites, and through goodness knows what other wonders, someone is honestly expecting to interest an intelligent, inquiring mind in an entry-level license for the exciting (?) world of ham radio where they have to chirp out a conversation over radio Moscow on 40 meters?! Until this all changes, ham radio is in trouble.

Wayne, please keep up the fight. You are right, like you were about FM and are about computers. I just wanted to let you know some of us do indeed agree with you and appreciate your foresight and efforts.

Larry Jack KL7GLK
Annapolis MD

UNFAIR REVIEW?

The July, 1983, issue of *73*, Mr. Jenkins, carried your review of our Radio School beginner tape course. I would like to discuss this review with you for further edification about our code-training program. Your opinionated review contains several misstatements which I would like to correct. Your review also does great disservice to anyone attempting to bring more young people into the ranks of amateur radio.

First of all, get my callsign correct. It is WB6NOA.

Your statement that the character speed per individual letter is slower than 10 or 15 wpm for our beginner tapes is not correct. Our tapes were generated by the same computer specifications that the Federal Communications Commission outlined in their CCITT Recommendation R.140. Our beginner 5-word-per-minute characters are sent at exactly 13 words per minute with longer spaces in between each character to slow down the speed to 5 wpm. We agree with you that students should learn the characters at an initial higher (13 wpm) character speed so that they do not need to relearn the letters while tackling the General-class license.

Your purely personal statements about random letters versus sentences should not have entered into an objective review about the code-learning process. Our tapes specifically train students to learn how to send and receive code over the air, and to pass typical over-the-air FCC-type QSOs. Although random letters certainly are harder to memorize, our tape courses are designed so that the students should have to only play each individual cassette three or four times before going on to the next one. When the student is beginning to memorize one cassette, that's a signal to go on to the next one. This is precisely why we have four individual cassettes, each 1½ hours long, as opposed to a single tape cassette, in learning the code.

Our code-teaching techniques have been tried and proven to over 4,000 graduates of our college classes here on the West Coast. We watch the students progress through the tapes and monitor their progress carefully. Your personal observations are obviously not based on actual classroom instruction.

As a fellow journalist, I would caution you from taking the high and mighty approach to objective product evaluation. Unless you are an acclaimed code-teaching expert, your opinions and observations in print are only one man's view of a product. Did you try it in a classroom situation? Did you give the tapes to the kid down the street who had been struggling with the code, and did you follow up to see whether or not these tapes kept his interest? Are you aware of the popularity of stereo cassette players that kids take with them everywhere? Have you actually tried listening to the tapes while going to work to fully appreciate the second-track narrated channel?

Your review should never have been printed because it is purely a personal evaluation of a code-learning concept that you, as an old-timer, might not like. I would remind you that your publisher (if you really are on the staff of *73*) has long preached the need for getting more kids into ham radio. This fresh new approach of code learning is indeed working in getting kids to listen to the tapes.

After all, one of the hardest parts of learning the code is simply keeping an interest in practicing every day. You missed that one completely in your personal review of our product—you failed to mention that these tapes were indeed "different" than other tapes and that they do keep a person's interest to continue playing them on a daily basis.

Mr. Jenkins, as a journalist, you are a discredit to the art of properly evaluating a product in print. I have probably logged thousands of words more than you in print, and I would hope that you would take some friendly advice and know what the hell you are talking about before sitting down at your typewriter and tearing down a proven code-learning method that could very well lure more kids and adults into ham radio.

You obviously didn't even get to the last tape—it specifically prepares students to pass their FCC Novice-class test by duplicating the exact tone and dit-dah ratio, and using similar type format material to that which the FCC uses. If the Novice applicant chooses to be tested by a fellow amateur radio examiner, there are several messages that meet FCC-published specifications that the examiner might draw upon. You also failed to mention that we have complete code courses for the new volunteer examiner that meet published FCC specifications for all levels of licensure.

Any time you are out here on the West Coast, please don't hesitate to stop by one of our evening college classes. Here you will see the new generation of amateur radio operators. These are positive-thinking people that get the best out of any product offered. Rather than sitting back and taking pop shots at equipment or magazines or writers that they might not care for, each of our students concentrates on the positive and gets the best out of what amateur radio writers, manufacturers, and instructors have to offer.

You should sit in on one of our classes—you very well could learn something and also a fresh approach to a positive outlook on anything that will assist more people into joining the ranks of amateur radio.

Gordon West WB6NOA
Costa Mesa CA

I appreciate your comments and would like to assure you that there was no intent to belittle you or your product in my review. Although you seem to have focused on the negative comments, I did applaud the production and organizational features of your tapes, which I felt were done very well.—Avery Jenkins WB8JLG.

MALPELO ISLAND

Off the west coast of South America, in the general direction of the Galapagos Islands, the tiny island of Malpelo rears from the Pacific. This uninhabited rock is far enough from the coast of Colombia to qualify as a separate "country" under DXCC rules. So Malpelo attracts an occasional DXpedition. Such a trip is scheduled for this month.

The island of Malpelo has been steadily moving up the list of the most-wanted DXCC countries, since the last DXpedition several years ago. Malpelo even entered the Top Ten in 1983. But Colombia restricts access to Malpelo, so they won't have to rescue stranded DXpeditioners off the rock. A fortuitous combination of circumstances opened the door to Malpelo this year.

The national amateur radio society of Colombia, the Liga Colombiana de Radioaficionados (LCRA), is celebrating its 50th anniversary this year. And a high government official, who happens to be a ham-radio operator, has secured the assistance of the Colombian Navy for transportation and logistical support.

This assistance should facilitate a long-time goal of Malpelo DXpeditioners: a radio station on the top of the island. The only landing area on the entire island is a small "beach" on the southeastern corner. High cliffs surround this "beach," which actually is a steeply sloping pile of loose rocks. Even climbing to the top of the island is a formidable task. Carrying radio equipment, antennas, generators, and fuel is out of the question. So previous DXpeditions have operated from the beach, much to the chagrin of West Coast and Japanese DXers. For the enormous bulk of the island blocks the beach radio communications to the north and northwest: W8 and 7 and JA.

The magnitude of this problem can be seen from the "most-wanted" statistics from *The DX Bulletin* (306 Vernon Avenue, Vernon CT 06066). In 1982, Malpelo was the 11th most-wanted country overall. However, many more West Coast and JA DXers need HK0. Malpelo ranks as 4th most wanted in W6, 2nd in JA, and 1st in W7, ahead even of China! On the other hand, Malpelo ranks only 16th among W4 DXers. A station on top of the island, without enormous cliffs in the way, would be a godsend to the Pacific DXers.

The LCRA is taking precautions in case the Navy helicopters are unable to set up a station on the top (see why having the Navy on your side helps?). The LCRA operators have been soliciting propagation information, schedules, and frequencies for those parts of the world which especially need a Malpelo QSL card. DX clubs and individuals have sent suggested operating schedules and bands to make the best use of the 5 planned days of operation. With careful planning and cooperation from other amateurs, the LCRA group could handle much of the demand for Malpelo even from the beach.

The details: The DXpedition is sponsored by the Liga Colombiana de Radioaficionados in coordination with the Colombian Navy. The amateurs will all be LCRA members, all HK licensees. The callsign will be HK0TU, QSL via HK3DDD. Projected frequencies are CW—1825, 3505, 7005, 14025, 21025, and 28025; SSB—1825, 3795, 7085, 14185, 21295, and 28595. Satellite and 2-meter gear will be along as well.

The Colombian amateurs are keeping busy during the 50th anniversary of their national society. In addition to their Malpelo DXpedition, LCRA is sponsoring a special certificate to amateurs who work Colombian stations with 5K and 5J prefixes in 1983. Work any 8 5K or any 8 5J prefixes (they can't be mixed) and send copies of the QSLs to LCRA, PO Box 584, Bogota, Colombia, for the free certificate.

Our thanks to Fred Laun K3ZO (see photo) for this information.

SPRATLY CONTINUED

The rescue of Baldur DJ6SI (see this column, last month) and the other survivors of his ill-fated DXpedition did not end the story of Spratly, 1983. First, there were the mysterious CW signals, without callsign, saying that Baldur's group had been picked up by a Russian submarine. Some Southeast Asian amateurs fear a radio hoax, one with the element of fun removed. More serious, however, was the reaction of the German press to the disaster.

The sudden, unexplained disappearance of a government counterespionage agent (for such was Baldur) attracted the attention of the press quickly, enough so that Baldur's wife is afraid to go outdoors. But the problem multiplied when the survivors were finally pulled from the sea.

German "experts" said the group could not have survived almost ten days in the uncovered dinghy, because of the high temperatures and the lack of water, food, and clothing. These experts noted the remarkably good physical condition of the four survivors and suggested that they had had something to eat in the past ten days.

The rumors of cannibalism coupled with the strange-sounding mission of this counterspy whipped the German press into a frenzy, and Baldur and his family were hounded at every turn. The rumors are, of course, nonsense.

"Experts" might suggest the survival time of an "average" citizen in similar conditions, but they cannot state that the party could not have survived. Thousands of survivors of torpedo attacks in the North Atlantic will attest that survival at sea in a small boat is more a matter of mental attitude and common sense than the dictates of experts.

And Baldur's group took great care to increase their chances of survival. Knowing that dehydration was the most serious problem, the group poured seawater over their bodies, to reduce their temperatures and decrease the body water lost through sweating. They carefully avoided drinking any seawater, which actually dehydrates the body and can be fatal if taken in the late stages of dehydration. The members of the DXpedition avoided unnecessary talking and kept their lips pressed together, to reduce water loss through the mouth. They conserved their energies, not wasting effort in rowing, flag waving, or other emotionally satisfying but unproductive activities.

In short, they did exactly what they had to do to survive: conserved their slender resources as long as possible. Four of the five who entered their dinghy survived the ordeal, and Gero DJ6EI, who didn't make it, was the least physically fit in the group.

Nevertheless, the nonsense continued, much to the chargrin of Baldur and his family. And he is still out the cost of all the equipment, without a word out of the Vietnamese government, not to mention the tragic loss of life.

The "Other" Spratly DXpedition

Meanwhile, while the controversy surrounding the DJ6SI DXpedition rages, another amateur group made an assault on Spratly, somewhat more successfully. In early May, Chito Kintanar DU1CK hitched a ride with the Philippine government to a Philippine-controlled island in the Spratly group, Thitu. This island is under the claimed and actual control of the Philippine government, as indicated by the well-maintained airstrip. Because Thitu is so close to the main group of Philippine islands, any amateur radio operation from Thitu would count for DU-Philippines, not Spratly.

But Chito didn't operate from Thitu. He pushed off in inflatable rubber rafts with a pack of scientists and motored to an island off Panata Cay. The stated purpose of the trip was the establishment of a wildlife preserve, especially for undersea life. Chito went along to provide emergency communications from the remote cay—and to make an occasional DX contact in the absence of an emergency.

Chito did indeed get radios and antennas to the island in the Spratly group and did make some radio contacts from the island. Limited antennas and generator problems restricted the operation to list-style, often controlled by DU9RG. A couple thousand amateurs, mostly in Asia, worked 1S1CK.

Some amateurs feel the operation should count only for the Philippines, as the Philippine government provided the transportation and "protection" of the party from start to finish. While the island where Chito operated was technically "unadministered," it was clearly under the control of the Philippine government while Chito operated, and thus should not be considered Spratly.

On the other hand, the Philippine government declined to issue a DU license or callsign for the island, citing "international repercussions." On this basis, Chito claims the use of the unofficial "1S" prefix and hopes his DXpedition will count for Spratly, not the Philippines.

Whatever the outcome of the debate as to which DXCC "country" Chito was in, Chito says he will be back again before the end of 1963, World Communications Year. A few more lucky amateurs might be able to put a 1S1CK QSL card on their wall (see card).

Meanwhile, all is not quiet on the home

Fred Laun K3ZO (left) with Harvey W2IYX, editor of the Long Island DX Bulletin. *Fred announced the Malpelo DXpedition this month.*

A few lucky amateurs "got on the list" and worked 1S1CK this May. Will it count for DXCC credit for Spratly?

front. In the wake of the disastrous Spratly Island trip by Baldur DJ6SI, several prominent DXers began calling for the deletion of DXCC credit for the Spratly Islands. Deletion of DXCC credit for the Spratly Islands would eliminate any incentive for amateurs to operate from the islands.

Reaction to the proposed deletion of credit for Spratly was as expected: those amateurs who had a Spratly card on the wall were totally against the idea; those amateurs who still had Spratly on their "wanted" list would be pleased to see the credit deleted. The latter group would have one less country to work, should credit for Spratly be eliminated. In fact, an amateur could actually get on the Honor Roll as a result of such an action, without working anyone!

Here's how it works. In the summer of 1983, the DXCC country count stood at 315. To be on the Honor Roll, an amateur must have at least 306 confirmed DXCC credits. The elimination of Spratly would lower the current country count to 314, and the Honor Roll cutoff to 305. An amateur who had 305 countries confirmed (but not Spratly) would gain Honor Roll status through the back door, without even entering his shack! Such are the absurdities of the ARRL DXCC Honor Roll!

Why delete credit for Spratly? Many members of the DX community were shocked by the deaths of the two West Germans during the DXpedition attempt, shocked enough to suggest removing the major incentive for amateurs to visit that corner of the South China Sea.

On the other hand, those who wanted Spratly retained (including many Californians, with Spratly cards on the wall) argued that DXCC credit should not be withheld simply because radio operation there was dangerous, or because of transportation difficulties. After all, amateurs have met and surmounted such obstacles to DX for years, and the deaths of two amateurs, although regrettable, was no reason for deletion.

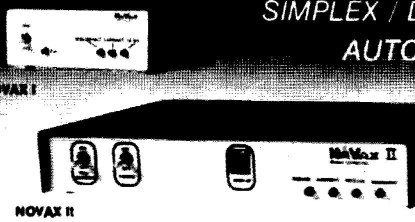
The pro-deletion amateurs, unable to use their real reason, fell back on deletion for reason of "significant change in administration." In other words, Spratly, which used to be a scattered assembly of worthless islands, should not now be a DXCC credit because the surrounding countries have taken a sudden interest in possible oil deposits under the island group.

The pro-delete amateurs, including those who have worked Spratly, and thus have nothing to gain, do have a point. The Spratly of Don Miller's day is a far cry from the heavily armed and vigorously protected islands today. But if we were to delete every country which has undergone a "significant change in administration," we would have to delete dozens of DXCC countries.

Whatever the outcome of the decision, for or against deletion, Spratly will remain a very special place for radio amateurs. The Spratly group has been the site of more trouble and controversy than any other such archipelago. Yet there is no question that any signal with a 1S prefix will command attention on the DX bands.

Introducing our Latest Model — NOVAX II

SIMPLEX / DUPLEX AUTOPATCH



NOVAX II

NOW TWO MODELS TO SERVE YOU BETTER

YOUR OWN PRIVATE AUTOPATCH

NoVax
MOBILE CONNECTION

NOVAX interfaces your standard 2 meter; 220; 450; etc. Base station and telephone, using a high speed scan switching technique so that you can direct dial from your automobile or with your HT from the backyard or poolside — Automatically ... Easy installation transceivers, featuring solid stats switching, offer best results ... Available interfaced with an ICOM 22U.

FEATURES	NOVAX I	NOVAX II
• 3 min. Call duration timer	YES	YES
• Up to 46 sec. activity timer	YES	YES
• Single digit Access Control	YES	NO
• DTMF (Touch Tone)* phone connection	YES	YES
• 4 digit Access Control	NO	YES
• Toll Restrict	NO	YES
• LED Digital Display	NO	YES
• Vinyl covered alum. case size	5" x 6" x 2"	10" x 8" x 1¾"
• Directly Interfaces with Repeater	NO	YES
• Rotary Dial System (incl. Last digit dial)	NO	YES—"Option"
• Ring Back (reverse autopatch) "Option"	YES Kit	YES—Wired

FCC

Calling the current regulations "archaic" and "unsuitable," the FCC changed the rules defining amateur transmitting power and how it is measured. Instead of input power, the new regulations call for the measurement of power output. Maximum power out is restricted to 1500 Watts.

Parts 2 and 97 of the Commission's Rules and Regulations, 47 CFR Parts 2 and 97, are amended as follows:

PART 2—[AMENDED]

§ 2.106 [Amended]

1. In § 2.106, under the heading "NG FOOTNOTES," the heading of the table in Footnote NG 15, paragraph (a)(4) is revised from "Maximum DC plate input power in watts" to read "Maximum transmitter peak envelope power output in watts".

2. In § 2.106, under the heading "U.S. FOOTNOTES," Footnote US7, the introductory paragraph is revised to read as follows:

US7 In the band 420–450 MHz and within the following areas, the peak envelope power output of a transmitter used in the Amateur Radio Service shall not exceed 50 watts, unless expressly authorized by the Commission after mutual agreement, on a case-by-case basis, between the Federal Communications Commission Engineer-in-Charge at the applicable District Office and the Military Area Frequency Coordinator at the applicable military base:

* * * * *

PART 97—[AMENDED]

3. In § 97.3, paragraph (t) is revised to read as follows:

§ 97.3 Definitions.

* * * * *

(t) *Transmitting power.* The radio frequency (RF) power generated by operations of an amateur radio station, including the following:

(1) *Transmitter power.* The peak envelope power (output) present at the antenna terminals (where the antenna feedline, or if no feedline is used, the antenna, would be connected) of the transmitter. The term "transmitter" includes any external radio frequency power amplifier which may be used. Peak envelope power is defined as the average power during one radio frequency cycle at the crest of the modulation envelope, taken under normal operating conditions.

(2) *Effective radiated power.* The product of the transmitter (peak envelope) power, expressed in watts, delivered to an antenna, and the relative gain of the antenna over that of a half-wave dipole antenna.

* * * * *

4. Paragraph (b)(2) and the introductory paragraph of (b)(7) of § 97.61 are revised to read:

§ 97.61 Authorized frequencies and emissions.

* * * * *

(b) * * *

(2) Operation shall be limited to:

Areas	Maximum transmitter peak envelope power output in watts			
	1900 to 1925 kHz, day/night	1925 to 1950 kHz, day/night	1950 to 1975 kHz, day/night	1975 to 2000 kHz, day/night
Maine, Massachusetts, New Hampshire, Rhode Island	150/35	0	0	150/35
Connecticut, Delaware, District of Columbia, Maryland, New Jersey, New York, Pennsylvania, Vermont	300/75	0	0	300/75
Kentucky, North Carolina, Ohio, South Carolina, Tennessee, Virginia, West Virginia	750/150	0	0	750/150
Florida, Georgia, Illinois, Indiana, Michigan, Wisconsin	750/150	150/35	150/35	750/150
Alabama, Arkansas, Iowa, Minnesota, Mississippi, Missouri	1500/300	300/75	300/75	1500/300
The remainder of the States and Territories	1500/300	1500/300	1500/300	1500/300

* * * * *

(7) In the following areas, the peak envelope power output of a transmitter used in the Amateur Radio Service shall not exceed 50 watts, except when authorized by the appropriate Commission Engineer-in-Charge and the appropriate Military Area Frequency Coordinator:

* * * * *

5. In § 97.67, the section heading and paragraphs (a), (b) and (d) are revised, and paragraph (f) is added, to read as follows:

§ 97.67 Maximum authorized transmitting power.

(a) Notwithstanding other limitations of this section, amateur radio stations shall use the minimum transmitting power necessary to carry out the desired communications.

(b) Each amateur radio transmitter may be operated with a peak envelope power output (transmitter power) not exceeding 1500 watts, except as provided in paragraph (e) of this section. Other limitations of this section and § 97.61 also apply.

* * * * *

(d) The peak envelope power output (transmitter power) of each amateur radio transmitter shall not exceed 200 watts when transmitting in any of the following frequency bands:

(1) 3700–3750 kHz;

(2) 7100–7150 kHz (7050–7075 kHz when the terrestrial location of the station is within Region 1 or 3);

(3) 21100–21200 kHz;

(4) 28100–28200 kHz.

* * * * *

(f) An amateur radio station may transmit A3 emissions on or before June 1, 1990 with a transmitter power exceeding that authorized by paragraph (b) of this section, provided that the power input (both radio frequency and direct current) to the final amplifying stage supplying radio frequency power to the antenna feedline does not exceed 1000 watts, exclusive of power for heating the cathodes of vacuum tubes. Limitations of paragraphs (a), (c) and (d) of this section and limitations of § 97.61 still apply.

6. Paragraph (d)(6)(ii) of § 97.77 is revised as follows:

§ 97.77 Standards for type acceptance of external radio frequency (RF) power amplifiers and external radio frequency power amplifier kits.

* * * * *

(d) * * *

(6) * * *

(ii) No amplifier shall be capable of amplifying the input RF driving signal by more than 15 decibels. (This gain limitation is determined by the ratio of the input RF driving signal to the RF output power of the amplifier where both signals are expressed in peak envelope power or mean power.) If the amplifier has a designed peak envelope power output of less than 1,500 watts, the gain allowance is reduced accordingly. For example, an amplifier with a designed peak envelope output power of 500 watts shall not be capable of amplifying the input RF driving signal by more than 10 decibels.

In an attempt to clarify the rules covering business communications in amateur radio, the FCC amended portions of Part 97. According to the Commission, the prohibition against business use was implied in the rules, but limits were not explicitly defined. The FCC's modification, as it appeared in the *Federal Register*, is reprinted below.

PART 97—[AMENDED]

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

1. In § 97.3, a new paragraph (bb) is added, after paragraph (aa), as follows:

§ 97.3 Definitions.

* * * * *

(bb) *Business communications.* Any transmission or communication the purpose of which is to facilitate the regular business or commercial affairs of any party.

2. In Subpart E of Part 97, entitled Prohibited Practices and Administrative Sanctions, a new § 97.110 is added, prior to § 97.112, as follows:

§ 97.110 Business communications prohibited.

The transmission of business communications by an amateur radio station is prohibited, except for emergency communications as defined in this part.

3. In Subpart E of Part 97, entitled Prohibited Practices and Administrative Sanctions, a new § 97.111 is added, between new Section 97.110 and present § 97.112, as follows:

§ 97.111 Limitations on international communications.

Transmissions between amateur radio stations of different countries, when permitted, must be limited to messages of a technical nature relating to tests, and, to remarks of a personal character for which, by reason of their unimportance, recourse to the public telecommunications service is not justified.

4. Section 97.114(c) is amended by deleting the second sentence thereof. As amended, § 97.114(c) reads, as follows:

§ 97.114 Third party traffic.

* * * * *

(c) Except for emergency communications as defined in this part, third party traffic consisting of business communications on behalf of any party.

As of August 31, 1983, the mail-back procedure for Novice examinations was eliminated by the FCC. The Commission's Final Order was adopted June 29, 1983, and amends the amateur regulations as follows:

Appendix A

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

1. The heading and paragraph (b) (1), (2) and (3) of § 97.28 are revised to read, as follows:

§ 97.28 Examination administration.

* * * * *

(b) Unless otherwise prescribed by the Commission, each examination for the Novice Class operator license shall be administered by a volunteer examiner. Each written test for the Novice Class operator license shall be prepared by the examiner from PR Bulletin 1035A (latest date of issue), entitled *Questions for the Element 2 Amateur Radio Operator License Examination.*

(1) When the applicant successfully completes examination Elements 1(A) and 2, he/she shall submit an application (FCC Form 610) to the Commission's office in Gettysburg, Pennsylvania 17325. The application shall include:

(i) The name and mailing address of the volunteer examiner administering the examination;

(ii) A description of the volunteer examiner's qualifications to administer the examination;

(iii) The volunteer examiner's certification that the applicant has passed telegraphy Element 1(A) and written test Element 2;

(iv) The signature of the volunteer examiner administering the examination.

(2) Each volunteer examiner must:

(i) Hold a current General, Advanced or Amateur Extra Class operator license issued by the Commission;

(ii) Be at least 18 years of age;

(iii) Not be related to the applicant;

(iv) Not be in an employer-employee, or employee-employer, relationship with the applicant; and

(v) Not own a significant interest in, or be an employee of, any company or other entity which is engaged in the manufacture or distribution of equipment used in connection with amateur radio transmissions, or in the preparation or distribution of any publication used in preparing for obtaining amateur station operator licenses.

(3) The volunteer examiner administering the Novice examination shall be responsible for the necessary supervision of the examination. A copy of the applicant's written examination papers must be retained in the volunteer examiner's station records for one year from the date the examination is administered.

* * * * *

2. Section 97.31(b) is revised to read as follows:

§ 97.31 Grading of examinations.

* * * * *

(b) Seventy-four percent (74%) is the passing grade for written examinations. Each element required for a particular license will be graded separately. Commission personnel will grade the written examinations, except the Novice Class Element 2 written examination, which will be graded by the volunteer examiner administering the examination.

Appendix B

Until FCC Form 610 is revised to include the certifications required by Section 97.28(b)(1), the statement on the current edition of Form 610 (December, 1981) must be modified. This should be done by writing in the appropriate underlined words as shown below:

Certification

I Certify That:

1. I am unrelated to the applicant (i.e. not a spouse, parent, child, stepchild, sister, brother, aunt, uncle, niece, nephew, grandparent, grandchild, in-law, stepbrother, stepsister, stepmother, stepfather.)

2. I am at least 18 years of age.

(3.) *I have examined the applicant and he/she has passed Element 2.*

(Check One)

☐ I have examined the applicant within the past 10 days and he/she has passed the five words per minute telegraphy examination.

☐ I have examined the applicant *in Element 1(A),* since he/she claims telegraphy test credit. The original FCC Form 845, Code Credit Certificate, is attached.

☐ I have not examined the applicant *in Element 1(A),* since he/she claims telegraphy test credit. Applicant's statement is attached giving the license number, expiration date, and class of commercial radiotelegraph operator license which qualifies him/her for credit.

73 INTERNATIONAL

from page 76

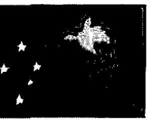
ing. Be certain that your car is in top-notch condition, especially the brakes, and that you have a quality spare tire. Even though the NAF (Norwegian Automobile Forrening) has its emergency patrols on all major roads, offering a high degree of technical assistance, it could save you a good deal of trouble and money. Check your insurance policy so that it will cover expenses if you should be unlucky enough to have an accident. Norwegians are very helpful, and most of them speak or understand English, German, and maybe one or two other languages.

The reason for mentioning these things is, of course, that they are so very easy to forget. Remember that some of the roads you will be driving on will be quite steep and narrow, and in places the road is cut straight into the mountainside, leaving the driver and passengers with a splendid view of the abrupt mountainside both below and above. It's amazing where you will find farms and houses. You will wonder, as we do, how they get there!

Now, what about mobile radio in Norway? After the description of what kind of landscape will greet you, you will also understand the lack of sufficient repeaters on 2 meters and 70 cm. However, those repeaters we do have cover quite a long range, some as far as 100 to 250 km because they are placed on mountaintops at altitudes up to 1 or 2 km. Repeaters are mostly concentrated around the densely populated areas and cover the main highways, so if you are planning to visit the western or northern part, bring your HF rig with you. It could be of great value and a good companion.

Standard voltage in Norway is 220 V ac, 50 Hz. The 2-meter band goes from 144.000 to 146.000 MHz. Repeater frequencies are from 145.600 to 145.825, with receive −600 kHz, and they use 1750-Hz tone-burst access. The callsign is sent in CW, and a complete repeater list and frequency list will be given to you when your license is issued.

I really hope that this information is of assistance to you, and on behalf of all Norwegian amateurs, I wish you a hearty welcome to Norway; we really hope you will enjoy your stay here. Have a good vacation.



PAPUA NEW GUINEA

Siegi Freymadl P29NSF
PO Box 165
Rabaul, Papua New Guinea

Rabaul is one of the most strikingly situated towns in the world. It has been built inside a still-active volcano. The magnificent harbor, Rabaul's reason for existence, resulted from successive large eruptions and the eventual collapse of large volcanoes which were formerly located there. The hole remaining after this event, 12 by 8 kilometers across and up to 500 meters deep, contains the harbor and the main part of the town. It is in fact a volcanic caldera. Because of that, it is a potential site for future eruptions and a center of seismic activity.

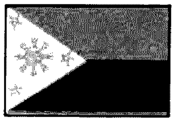
Because of the publicity given in recent months to the possible destruction of Rabaul by a volcanic event, I have decided to devote this month's column to emergency services agencies in the area.

1) The National Emergency Services were formerly under the control of the Post and Telegraph Department, but approximately two years ago it was put under Defense Force control. One officer is looking after the headquarters at Rabaul, situated in a picturesque location on top of Namanula Hill, overlooking Rabaul. An emergency net between NES Rabaul and 29 stations throughout the New Guinea Islands is operated on a twice-daily fixed schedule at 0715 and 1915 local time on 3732 MHz. One of the stations checking into the net is P22DQ, the base station at the Volcanological Observatory Rabaul. Equipment used are Codan 7515 SSB sets, and the antenna at NES Headquarters in Rabaul is a dipole. Rabaul keeps a continuous watch from 0700 until the end of the last radio schedule at 1915. In case of an emergency, the officer is on 24-hour standby. He also provides a phone patch when needed. Operations Center is Defense Force Headquarters in Port Moresby; other NES bases are at Lae, Madang, Wewak, and Manus. The Rabaul officer was trained as communications officer by the Defense Force. He hopes for bigger communications sets with more crystals and better antennas in the near future. It is also to be hoped that the lone officer maintaining vigil at NES Rabaul will receive additional staff to assist him.

2) Since independence, the national government has instituted a decentralization program to hand over more and more authority to the various provinces. One of the newly created departments is the Disaster Planning Unit under the East New Britain Provincial Government, which has been in existence for just over three months. A coordinator is at the head of the department and plans are still being drawn up to cover volcanic emergencies and tsunamis, earthquakes, erosion, floods, and drought. For communications, Philips 2m SSB sets are in use at the office and in cars. At this stage, the Disaster Planning Unit is still "finding its feet."

3) The Central Observatory in Rabaul is situated up on North Daughter, a dormant volcano, and there all the sophisticated monitoring devices for seismic and volcanic activities are housed. Also operated from there is the volcanological net on 6815 MHz at 0800 and 1400 local time, seven days a week. Stations at Manam, Karkar, Langiia, Talasea, Ulamona, and Esaia are on the network using SSB voice and P22 prefixes. An additional callsign, P22CF, is assigned for mobile use. NES has access to this net and the Central Observatory in turn has access to the NES frequency. Rabaul Central Observatory, Karkar, Manam, and Esala use 100-W Codan sets with cut dipole antennas. The rest are equipped with 25-W portable Codan sets using longwire antennas. All stations, except Central Observatory Rabaul, are powered by batteries, which are charged by one 12-V, 2.4-Amp Arco solar panel. A portable seismograph is also powered by solar energy. Installed at the residence of the senior volcanologist is a Kenwood 930S and a dipole antenna, and he uses this set to conduct the volcanological net on weekends. A four-stage emergency plan has been drawn up, the last stage being implemented when an event is imminent within a few days or as little as a few hours.

These are the agencies in Rabaul looking after emergencies. Strangely enough, no effort has been made to enlist the help of any radio amateurs in the area. It seems to me that amateurs could render valuable services in times of emergency. This was pointed out to the Coordinator of the Disaster Planning Unit and the Officer-in-Charge at National Emergency Services, Rabaul.



PHILIPPINES

Leo M. Almazan
PSC #1, Box 1471
APO San Francisco CA 96286

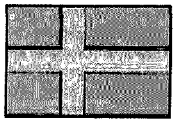
The amateur-radio scene in the Philippines is about the same as in any of the Third-World countries around the world. The growth is in the upswing because of the availability of VHF/FM hand-helds, so there are more VHFers than HFers. The hobby is now under scrutiny because of illegal users of 2m FM rigs.

The regulatory body in the Republic of the Philippines is the NTC (National Telecommunication Commission) under the Ministry of Transportation and Communication. At present, the amateur license structures are as follows: Class A—full privilege, 2000 Watts PEP; Class B—same privilege as Class A except 20-meter phone privilege (14.275 and up only), 1000 Watts PEP only; Class C—Novice class, phone privilege on 40 meters and 2 meters only, CW also both bands, 25 Watts only PEP.

The Philippine amateur scene covers most aspects of the hobby. There are DXers, RTTY and OSCAR enthusiasts, VHF/UHF aficionados, and of course good "old-fashioned" CW buffs. Last April, Manila Hamfest '83 was one of the highlights of amateur radio in the country. It was sponsored by the Ham Radio Philippines Ham Club. This active organization put on a tremendous show by inviting all or most of the different clubs and organizations in the Philippines. A plenary session was held to map out the future of amateur radio in the Philippines.

For prospective visitors to the country, a reciprocal license is easily obtainable, provided the visitor's country of origin has a reciprocal agreement with the Republic of the Philippines. All you need is a photocopy of your license, three passport-size pictures, and the necessary paperwork. Processing is from one to two days. Most American "recips" (most of them are stationed either at Clark Air Base or Subic Naval Base) can have their reciprocal license mailed to their local or APO/FPO address. In my case, it was mailed to both!

More information can be acquired through the Philippine Amateur Radio Association, PO Box 4083, 17th Floor, Philippine Communication Center Building, Ortigas Avenue, Pasig Metro-Manila, Philippines. Or if you are an American serviceman, contact the Central Luzon Amateur Radio Club (CLARC) located at the old Carmelite Hospital, Angeles City, just outside Clark Air Base, or call telephone number 55228 inside Clark and ask for Jerry McCracken or Leo Almazan for more information.



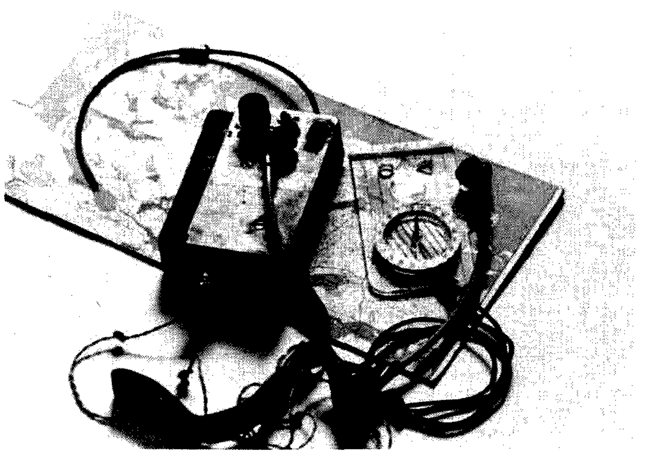
SWEDEN

Rune Wande SM0COP
Frejavagen 10
S-155 00 Nykvarn, Sweden

The Swedish television devoted a full hour program to ham radio a few months ago. Mr. Erik Bergsten SM6DGR has for many years produced a very popular program called "Technical Magazine." A recent series of programs has been about the development of radio and television from the very beginning up to today's satellite TV. Amateur radio got its full share of this. Erik brought up specialized communications modes like moonbounce (EME), meteor-scatter, SSTV, RTTY, contesting, etc., and also amateur-radio direction-finding (ARDF), popularly called fox-hunting.

Fox-hunting, European style, brings the ham operator out from the shack into the fresh air. Radio direction-finding as a sport among hams started in Sweden in 1947 and spread quickly within Europe in the 50s. The first Swedish Championships were held in 1952 by Vasteras Radio Club, SK5AA, a club celebrating its 40th anniversary this year.

Swedish hams SM5IQ, SM5AVC, and



The fox-hunter's weapon—receiver and compass. Photo by SM0EJY.

SM5CRD went on their first "missionary" trip to Norway in 1952 to spread the idea of fox-hunting. The first unofficial European Championships were held in Sarajevo, Yugoslavia, in 1958 and this sport has become very popular in East Europe. The World Championships are usually arranged by an East European country.

US Variety

In the US, direction-finding on two-meter FM has a growing popularity. For this, two-meter hand-held equipment with HB9CV antennas is used. I saw this demonstrated at a Minuteman Repeater Association meeting in Boston, Massachusetts, about a year ago. In the US, fox-hunting is of course (!) done by automobile.

Orienteering

ARDF is very similar to the so-called orienteering, which is a sport in which you run in the forest trying to find checkpoints that are marked on a very detailed map. You also have a compass to help you. This Swedish sport is spreading all over the world. The New England Orienteering Club in Massachusetts has been very successful in the US. In fox-hunting, the checkpoints are well hidden and you have to try to find them (usually five) by the means of a map, a compass, and a small direction-finding receiver about the size of a king-size cigarette pack. Frequencies used are between 3,500 and 3,600 kHz. The transmitters used are low powered, just 2 Watts or less, and the antenna is a short vertical wire hung up in a tree. Each fox transmits a series of dashes — — — — — i.e., M O; the longer the dashes, the easier it is to determine direction. The five foxes transmit two minutes each, one at a time. No. 1 fox starts by sending a series of M O E M O E for two minutes. The letter E, i.e., one dit, identifies the first fox. No. 2 fox follows by sending M O I M O I, etc. After ten minutes, you have one bearing to each transmitter. You then quickly (by running) change position and take the cross-bearing during the next ten minutes. It is not as easy as it may sound.

No Code Proficiency Needed

You do not have to be a ham to participate in fox-hunting and knowledge of Morse code is of course not necessary. You can identify the fox by the number of dits transmitted.

The development of automatic fox transmitters has facilitated the arrangements for a hunt. The old system required a minimum of five operators hiding in the woods and getting eaten up by the mosquitoes. These new automatic transmitters also give the successful hunter a slip on which the ID of the fox and the check-in time is printed. The hunter having proof of finding all five foxes in the shortest period of time is the winner. It sure is not always the fastest runner that wins. You must be accurate when you take the bearings.

Championships

In the Swedish as well as the Nordic, European, and World Championships in ARDF, the score is a combination of the results from both the day and the night hunt. The Swedish Championships this year took place in Eskilstuna, 90 kilometers west of Stockholm, in August.

The World Championships 1982 were going to be held in Bulgaria (LZ), but were postponed due to difficulties caused by the hosting country. The International Amateur Radio Union (IARU) Region 1 has developed international rules for amateur-radio direction-finding. ARDF is a very nice club activity, involving building and constructing the equipment and arranging the outdoor activities. Why don't you start this in your club? For further information, feel free to write to me (SASE or SAE + IRC, please). It is just a matter of getting started.

Claes SM0CTU taking bearings. Photo by SM0EJY.

TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan 107
Republic of China

I feel quite honored to have had many visitors this year. A common question often raised by visitors is "Why is there only one station—BV2A/BV2B—on Taiwan?"

For security reasons, ham activity has been restricted to a certain extent in the past. However, I feel the situation has gradually improved, and the future looks bright.

Amateur-radio operation is governed by the so-called "Special Telecommunications Regulations," which was revised on October 9, 1972. The regulations stipulate that a Chinese national must pass an MOC (Ministry of Communications) examination or possess a professional radio license to receive a ham ticket. Hams were at first allowed to operate only on 14 and 28 MHz, but since December, 1981, the 21-MHz band has been open. At present, there are still three operative bands available; other HF and VHF bands for hams are not likely to be opened in the near future. I found that some bootleggers had deliberately used my calls on 40 and 80 meters and had caused a lot of confusion.

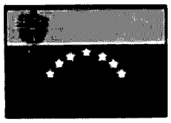
The examination consists of a test on fundamental electricity, radio principles, telecommunications regulations, and international radio regulations relevant to amateur-radio operation. A 13-wpm code-proficiency test is also required.

Obviously, the ruling is too simple to meet with the fast development of amateur-radio activities worldwide. I am given to understand that revision of the regulations is under way.

BV2A was first established in 1959 to operate on 20-meter CW only. In 1974, the ex-INDXA (International DX Association) of Maryland offered me a Heathkit 32A monoband transceiver to initiate 20-meter SSB operation with the callsign of BV2B. Later, W9ZNY lent me a hand and air-shipped a set of 203BA antennas from Chicago, which, in conjunction with the HW32A, has greatly improved my signal. I would like to thank those contributors for their assistance.

Although there is only one ham station on this island, I am sure that a great many young men like the unique hobby and they will come into hamland as soon as the restriction is lifted.

Many times, Chinese authorities have rejected requests for visitors' licenses, since we have no reciprocal agreements with any other countries. Recently, a group of Italian hams—I2DMK, I2BVS, I2PKF, and I2JQ of the Associazone Radiotecnica Italiana—applied for permission to operate their rigs for ten days in commemoration of World Telecommunications Year. This request is now under favorable consideration by Chinese authorities. If the official approval can be obtained, it not only will enhance closer friendship between hams of the world, but also will create a good beginning for radio amateurs on this island.



VENEZUELA

Caracas 1061-A
Venezuela

I sent an article on parabolic antennas to *73* as a contribution to help fellow amateurs in understanding the techniques that we'll be using during this new wave of radio communications. I'm convinced that with the advent of OSCAR 10 and other satellites that will follow, the use of frequencies above 2 meters along with new modes of operation will pervade the radio-amateur interest in the near future. Certainly parabolics at lower prices and of better materials will be bargains very soon. Just wait for the Direct-Broadcast Satellites which are practically standing in the launch pad. Anyhow, be prepared to handle at least a three-meter-diameter parabolic. In comparison with the most commonly used of today's HF antennas, the one-meter parabolic will be like a dipole and the three-meter parabolic will be like a three-element triband beam, so to speak. The worst thing is that the parabolic should be rotatable both in azimuth and elevation unless geostationary satellites were placed in orbit. For those liking fancy rigs and Molniya-orbit satellites, the bigger parabolics would be installed along with big rotators.

For us in Venezuela, having a parabolic on your own roof was prohibited because the communications authorities found out that some people were doing business with TVRO and video recorders. Anyway, since the present Minister of Communications (Francisco Lara YV5CBB) intends to perfect the present regulations, no doubt something will be done regarding this topic.

While writing on these matters, I tried to imagine how those great daring men in the world's history managed to explore, conquer, survive, or fight against men and nature to get freedom and liberty. I'm talking about David Crockett, Colon, Napoleon, Bolivar, etc. Can you imagine those men who, without electronic aids, went across the world in search of their dreams and fates?

A Venezuelan, Simon Bolivar, did it to liberalize Bolivia, Colombia, Ecuador, Panama, Peru, and Venezuela. For us Americans, it is easy to imagine how it was done, but let me tell you that South America is several times the size of Europe and that the Andes Mountains' altitudes are 5000 meters in Venezuela and up to 7000 meters in Bolivia. Can you imagine those resolute men crossing the Andes on foot, with horses and mules carrying weapons and food? Really not an easy task, and they did it not just once, but many times.

The Venezuelan territory offers infinite varieties in landscapes and in climate. All along her shores there are kilometers upon endless kilometers of sandy beaches. Temperature is high on the coast and on the plain. Being a Caribbean country, it is

easy to imagine how high the temperature is. Nevertheless, due to trade winds, the weather is not too rigorous in the northeast. The northwest is far warmer, and you may expect temperatures as high as 41 degrees centigrade at sea level and on the plains.

Toward the west and northwest, the Andes Mountains with the treeless plateaus lead you from the warmth of the coast to the coldness of the altitudes. The highest mountain in Venezuela is Pico Bolivar (Bolivar Peak) in Merida State with an altitude of 5007 meters (16,000 feet). About 36,000 square kilometers of the territory are crossed by the Andes. That's why there are so many VHF repeaters in this country. More than 60 have been licensed on 2 meters and 70 cm covering half the nation.

Toward the south is the Orinoco River with a host of wide and lazy tributaries. They snake through the ever-green, dense, warm jungle. The river is 2,140 kilometers long with a maximum width of 20 kilometers near Ciudad Bolivar, capital city of Bolivar State. The river depth varies from 80 meters to 100 meters during the rainy season from July to November. One of the most important branches of the Orinoco is the Caroni river in Bolivar (YV6). On a tributary of this river, the Churun, is the highest waterfall in the world, the Salto Angel (Angel Fall). Plunging 1500 meters, this fall was discovered in 1937 by an American pilot named James C. Angel. In my opinion, it is located in the most beautiful landscape in South America—which also is one of the oldest in the world (Precambrian—600 million years ago).

The territory south of the Orinoco is sparsely populated, with some small towns, several thousand aborigines, and only two cities with more than 150,000 inhabitants: San Felix and Ciudad Bolivar. That's why there are only three repeaters in the southern territory.

Some advice is in order: Do not expect to meet feathered indians or loincloth-wearing people when you arrive in this country. If you like to see indians, be prepared for a long trip toward the south. This country has the typical occidental style both in look and way of life. Caracas, the capital city, is a modern metropolis and one of the most beautiful places in South America. I will try to depict in future columns how the country is, by call areas.

REPEATERS

A list of the already-working VHF repeaters is shown in the box. With all those repeaters and links, you may travel across the country by car, rag-chewing hour after hour using HTs.

The topography surrounding Caracas is mountainous with altitudes as high as 2,300 meters. Near here is where the Andes end, after a long line of mountains that begin in the southernmost part of South America. The highest repeater sites in the Caribbean are, no doubt, in Venezuela. There are two such repeaters channeled at 147.000 (−600) and 147.180 (−600) MHz bringing DX possibilities from time to time. Today (June 24) I heard WD4EXH/KP2 (Mike) from Saint Thomas and HI8AEA from the Dominican Republic. Not very often, but yet not uncommon, it is possible to hear Curacao, Aruba, Puerto Rico, Colombia, Dominican Republic, Panama, etc., due to anomalous propagation—you know, ducting and similar things. Fortunately, the abnormal propagation sometimes lasts several days. Some very slow fading is expected, so should the signal be lost, just wait a while and try again after some minutes. I have heard also that somebody made contact through the 147.000-MHz repeater with a mobile traveling from Tulsa, Oklahoma, to Orlando, Florida. This kind of DX through 2-meter repeaters is not new. During 1976, I made contact with Juan PJ3JAV and I remember his signal was solid for several days. So, Caribbean DXers, aim your 2m antennas to Caracas and push the mike button, and if you hear the kerchunk, give us a call.

146.640	Maracaibo	147.970	Western

I have investigated the ham population and it seems to be 20,500 strong instead of 16,000 as I wrote previously. Up to this moment, 30,664 ham licenses have been issued. Thus, more than 10,600 were cancelled or lost due to several causes, including silent keys. There are around 3,000 active hams using all bands from 160 to 23 cm and all modes including SSB, RTTY, SSTV, etc. There also is some activity with current satellites although just a handful of Venezuelan hams are registered AMSAT members. They are Manuel YV5LW, Jose YV4CB, Wolfram YV4WT, Asvaldo YV6ASU, Jorge YV5FNG, Hector YV5BQO, Jose YV5GDX, Efrain YV4CLV, Edgar YV5ZZ, Augusto YV5AW, Gustavo YV5DRM, Coisme Gomez, Sven SM5CGA/YV5, Jaime HK9ASC/YV5, and this writer.

The foreign amateurs to operate from Venezuela number around 20. Some of them are Erwin OA4AJU/YV5, Mirella OA4ANS/YV5, Alfonso OA4APQ/YV5, Maria Isabel OA4CRK/YV5, James WD8AMY/YV6, Henry W8PLV/YV5, Rainer DL2GG/YV5, Sven SM4CGA/YV5, Claudio TI4CAM/YV5, Claudio LU5DND/YV5, and this writer.

COMMEMORATIVE AWARD OF 50TH ANNIVERSARY OF VENEZUELAN RADIO CLUB

Sponsored by Radio Club Venezolano, it will be granted to any amateur radio station which fulfills the rules.

Gold Endorsement Award

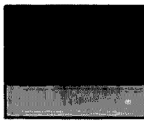
Application: No QSL cards but a log of contacts with twenty different Venezuelan stations with a maximum of three per call area plus one contact with radio club station YV5AJ. The application must be accompanied with a sworn declaration of rules fulfillment.

Silver Endorsement Award

Application: No QSL cards but a log of contacts with ten different Venezuelan stations plus one contact with radio club station YV5AJ. The application must be accompanied with a sworn declaration of rules fulfillment.

Time period: May 1, 1983, 0001 GMT to January 30, 1984, 2400 GMT; bands: 160, 80, 40, 20, 15, 10; modes: either SSB or CW or both; closing date: logs should be mailed before and no later than March 1st, 1984.

Award fee is four IRCs for postage and handling. Send to Radio Club Venezolano, PO Box 2285, Caracas 1010-A, Venezuela.



Guenter Schwarzbeck DL1BU in his test shack. About a third of his test equipment is shown. (Photo by Kurt Goldberger)

GUENTER SCHWARZBECK DL1BU

Everybody knows the symptoms of deciding on a new piece of equipment: self-conviction that something new has to be acquired, enthusiasm afterwards about the number of choices on hand, study of the manufacturer's specifications, consultations with friends, and maybe a hands-on test. But, irresistibly, uncertainty about the right decision develops during this process and one realizes how much subjective data and how little objective data one has for the decision to be made. And, in fact, can one really expect that the manufacturer will tell us about the birdies in his new transceiver, the effect of the switch-selectable preamplifier on the 3rd order intercept point, or the difference of antenna gains for competitive products under identical test conditions? And the statement, "Gain and F/B ratio cannot be published in *QST*," adds to the confusion of consumers rather than stimulating the publication of objective and comparable performance data.

It was most fortunate, therefore, that Guenter Schwarzbeck DL1BU began a series of test reports on radio equipment and antennas in the German *CQ-DL* magazine about 8 years ago. Since that time, he has gained a reputation for his test reports, and not only in Germany. Being a professional in electrical engineering and an avid ham for more than 45 years, he has set up a laboratory with a whole range of test and measurement instruments for this purpose (see photo). The framework of his test procedures and a thorough discussion of his measuring methods were published monthly in the *CQ-DL* magazines July through October, 1976, and in June, 1977. In the past, test reports appeared on (among other things) the Astro 150, IC-730, FT-ONE, TS-930S transceivers, the Datong FL2 filter, coaxial switches and relays, a comparison of the QSK features of Ten-Tec, Cubic, and Drake equipment, and the TH6DXX, TH3MK3, KT34, KT34X, FB33, and FB53 antennas.

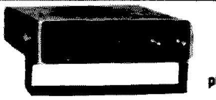
In the beginning, Guenter wrote a number of articles about the physics of ham radio and equipment and propagation, too. But since then, more and more emphasis has been placed on the new transceivers and antennas appearing on the market. Today he is practically drowning in equipment offered to him for testing. And he considers it a challenging task not only to produce unambiguous measurements, but also to publish them in a way that is understandable and meaningful for

the average reader. The toughest job, however, he thinks, is the evaluation of HF antennas. Not because of the physics involved, but due to the sometimes misleading information given by some manufacturers and the nonobjective, emotional attitudes expressed towards certain types of antennas.

Most of his publications are written in German, but casual translations, for example in the British *RadCom* magazine, are spreading the word around. Due to the growing interest in his work on the international level, Guenter is looking for opportunities to publish his reports more regularly in an English-language magazine. In order to leave him some time for his other hobbies—like high-speed CW, including contests (most of which he wins), discussing technical topics, and rag-chewing with friends—a more regular cooperation with a technical translator and fellow ham probably would serve the needs of his international audience best.

If you are interested, you may contact him by mail (6901 Schoenau-Altneudorf, Federal Republic of Germany) or meet him on 14317 kHz Sundays around 0800 hours UTC in the DL/VK net. Although he is a high-speed CW man, he can be heard there quite often now ... since he got a mike a few years ago.

SYNTHESIZED
SIGNAL GENERATOR



MADE IN USA

MODEL SG100D
$349.95
plus shipping

• Covers 100 to 185 MHz in 1 kHz steps with thumb-wheel dial • Accuracy 1 part per 10 million at all frequencies • Internal FM adjustable from 0 to 100 kHz at a 1 kHz rate • Spurs and noise at least 60 dB below carrier • RF output adjustable from 5-500 mV at 50 ohms • Operates on 12 Vdc @ 1/2 Amp • Available for immediate delivery • $349.95 plus shipping • Add-on Accessories available to extend freq. range, add infinite resolution, voice and sub-audible tones, AM, precision 120 dB calibrated attenuator • Call for details • Dealers wanted worldwide.

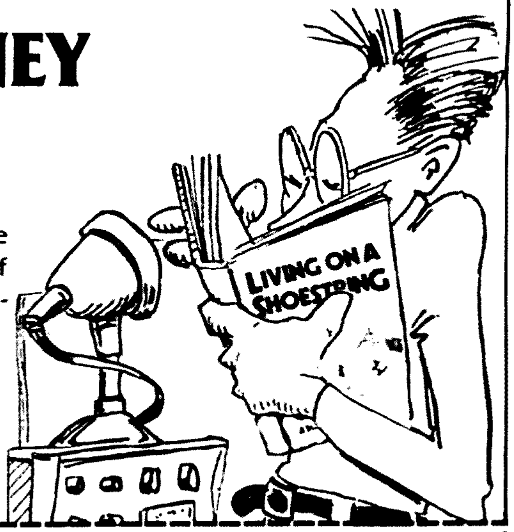
MAKE SAVING MONEY A WAY OF LIFE



With **LIVING ON A SHOESTRING:** A Scrounge Manual for the Hobbyist. Almost anything you find can be put to good use if you follow the techniques of a master scrounger. George Ewing WA8WTE shows you how to:

- Find electronic parts
- Locate tools and other surplus
- Scrounge by the rules
- Read up on scrounging
- Scrounge a vehicle
- Scrounge a place to live

Cartoons and case histories of scroungers add a humorous touch. With **LIVING ON A SHOESTRING**, you can't always get something for nothing, but you can certainly get it for less.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

WHAT'S GREEN REALLY UP TO?

A few years ago, I wrote in my editorials in *73* my prediction that microcomputers would one day grow to the size of the car industry. I also pointed out that this growth was a golden opportunity for those interested in getting rich.

Based on that concept, I first started *Byte* magazine as a vehicle to help that industry to speed up its growth (*Byte* was the largest consumer magazine in America last year) and then *80 Micro* to help entrepreneurs get a piece of the action (the third largest consumer magazine in America last year).

The computer field is still in its early growth stages, so there are lots of opportunities yet to make fortunes there. You'll see me starting even more magazines to help it grow and deal entrepreneurs in on the action.

One of the benefits to me of amateur radio has been the interest I've gained in travel. Talking with hams in virtually every country of the world has interested me in getting to personally see their countries and meet them in person. And in each country I visit, I can't help but *compare their* quality of life with that we enjoy in America.

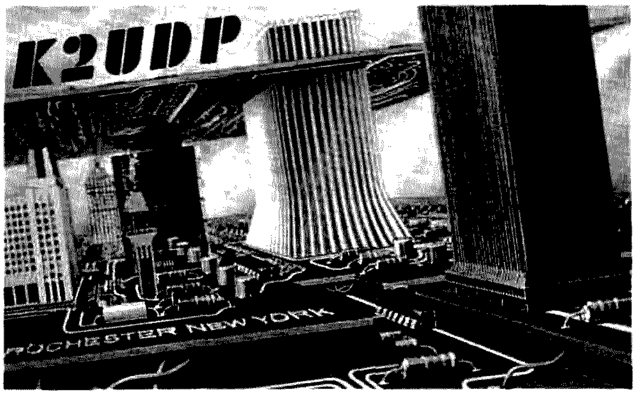
Most of the Third-World countries have it pretty tough. They are prisoners of poverty, ignorance, and, as a result, tyrannical governments. We've tried throwing money at these countries, but that is divided up among the tyrants, providing little for the people. The answer, of course, is to provide them with education. In the long run, this will change the patterns of poverty.

That, my friends, is Green's Goal. It is my intention to provide the entire world with a high-quality, low-cost education, using high-technology techniques. I'll make this prediction: Education is going to be a marketable product and the industry manufacturing and selling this product is not only going to be larger than the car industry, but also larger than OPEC.

Being one of the early ones to see what is coming, I'm in a position both to help this come about and also to profit from it, as I did with computers. Indeed, I think several thousand brainwashed ARRL members were pretty surprised when they heard that I'd sold my magazines for $60 million. That didn't tie in very well with the League theory that I'm a blundering idiot who is destroying amateur radio.

You know, I got started in hamming 45 years ago and it is depressing to me to get on the air and see how little things have changed in all that time. About the only significant changes are sideband and repeaters (both of which I helped make happen with my magazines). It's getting time for some major changes to bring amateur radio into our high-tech age. Perhaps, from that viewpoint, it is time to "destroy" amateur radio—and that seems to be the ARRL position. I want hamming to progress, to be able to provide the quality of communications modern technology allows, and not be stuck fifty years in the past, held to our ancient Morse-code traditions inflexibly.

Continued on page 108



QSL OF THE MONTH

The high-tech city: That's Rochester, New York, and this winning QSL card from the Rochester Amateur Radio Association reflects Rochester's claim to fame. According to the Department of Commerce, this city leads the nation in high-technology exports, and RARA is proud of amateur radio's contributions to the community. There is no doubt that the scene makes for a striking QSL card. It represents the way an area can be linked, not only by streets and sidewalks, but also by the communications network provided by ham radio.

To enter your QSL card in *73*'s QSL of the Month contest, put it in an envelope with your choice of books from *73*'s Radio Bookshop and mail it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not in envelopes or without a book choice will not be considered.

Construct the Callsign Power Supply

KA1QZ put together aesthetics and electronics to produce a power supply that gives you more than good regulation.

Limited funds along with the hassles of apartment living and QRO hamming forced me to explore QRPp operation as a last-ditch attempt to preserve some form of my ham radio hobby. A friend's donation of a Ten-Tec PM-3 5-Watt CW transceiver and a spare 12-V battery put me on the air while keeping QRM from my neighbors to a minimum. Eventually the battery expired, and I made the decision to dust off the soldering iron and build a small power supply rather than spend precious allowance for expensive batteries. I also wanted to have a power supply that would provide the necessary power for an Argonaut which I eventually hope to acquire.

Visions of state-of-the-art ham equipment with its fancy lights and whistles inspired me to construct something similar in terms of a functional conversation piece for my QRP station. Apart from a power supply to power the rig, few ham shacks can be found without a clock, so a digital-clock module seemed the ideal complement for the supply. Much to my delight, I found that the clock chips currently on the market were inexpensive enough to allow me to purchase a pair: one a 12-hour format and the other a 24-hour format. Thus, I could have the 12-hour clock set to local time and the other to UTC. Finally, a late-night flash of inspiration led me to complete the power supply/clock console with a callsign that lights up when the supply is on. Combining all into a Ten-Tec-style enclosure resulted in a real conversation piece as well as a multi-functional addition to the QRP station. Most important, the whole project did not bankrupt me and required only a few evenings worth of time.

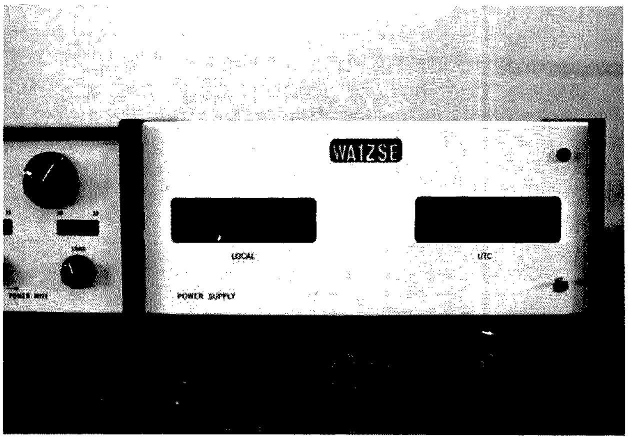

Photo A.

The Power Supply

The power supply was designed to provide an adequate amount of power at minimum cost for QRPp rigs in the 5-to-6-Watt class with some reserve for 12-V station accessories. The PM-3 requires 480 mA in the transmit mode, but the Argonaut draws 1 Amp in the transmit mode. The ac power supply available for the Argonaut delivers 13 V ± 0.5 V at 1.2 A. I decided that a 13-V supply capable of delivering 1.5 A to 2.0 A output current would be desirable.

The next step was to select an IC regulator. I ruled out the 78XX series of fixed-voltage regulators. Even though these regulators can be used for current output in excess of their guaranteed 1-A rating, it is not recommended operating these regulators at or above their maximum current rating for extended periods of time.

To my knowledge, there are no readily-obtainable 2-A IC regulators. Going to the 3-Amp and above class of regulators was more money than I was willing to part with, especially when that much current capacity wasn't really needed. To utilize the full current capacity of these large regulators would also require a larger, more expensive transformer. A good compromise for this project was reached by using the LM317 variable-voltage regulator.

The LM317 is a 3-terminal positive voltage regulator with a guaranteed current output of 1.5 A. The output voltage is variable from 1.2 V to 37 V. Two external resistors are used to set the output voltage (see Fig. 1). The regulator output voltage is given by the equation: $V_{out} = V_{ref}(1 + R2/R1) + I_{adj}R2$.

Vref refers to the 1.25-V reference voltage generated between the output and the adjustment terminal (terminal 2). The constant voltage across R1 causes a constant current to flow through output resistor R2, giving the desired output voltage. For most purposes, the last term in the equation can be ignored since the Iadj term has units

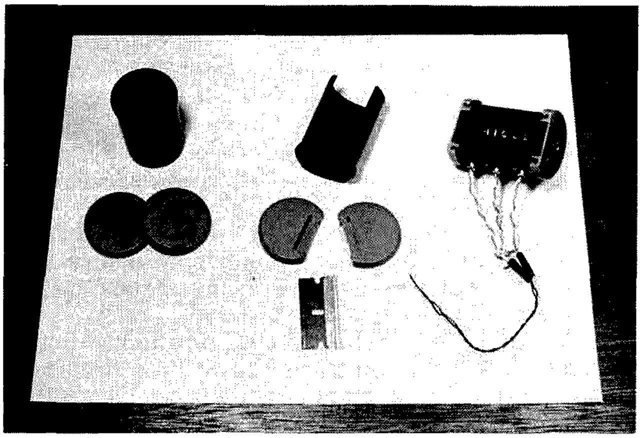

Photo B. Construction of callsign housing using 35mm plastic film cans. Completed unit is shown on the right. (My call then was WA1ZSE.)

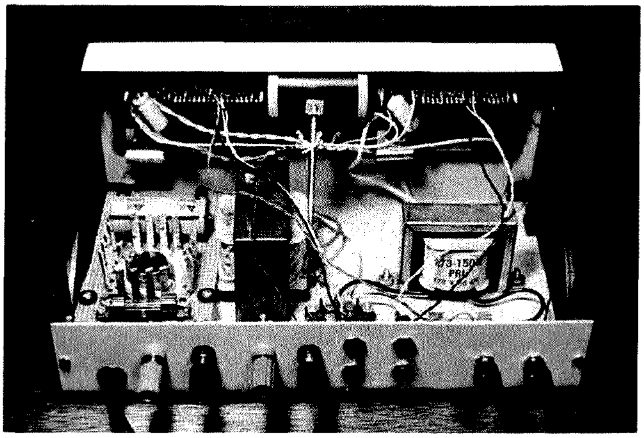

Photo C. Assembly of components into enclosure. Transformer on right powers both clock chips. QRP power supply is on the left. Two sets of binding posts allow for connection of QRP rig and an additional 12-V station accessory. Knobs at far right on the back panel are clock-dimmer pots (optional). The callsign housing in the center background is held in position by a 4″ × ⅛″-diameter machine screw anchored to the bottom of the enclosure. An L-shaped bracket attaches the callsign housing to the mounting screw.

of microamps making the entire term insignificantly small.[1] The equation can be arranged to allow for easier calculation of the R2 value, given a desired output voltage and assuming R1 = 220 Ohms—an arbitrary but common value: R2 = (Vo − 1.25)220/1.25.

For a 13-V output in my supply, R2 = 2068 Ohms. A slightly higher value of R2 (say an additional 100 Ohms) may be necessary to offset the tolerance error of the resistors if an exact output of 13 V is desired. However, none of these values is critical as long as Vo lies within the 12-14-V range required by most "12-V" rigs.

Although I used the more expensive TO-3 version of this regulator, the TO-220 package would work equally well provided it is mounted to an adequate heat sink.

The complete power supply circuit is shown in Fig. 1. Regulator circuit protection is provided by the current-limiting feature of the LM317. Overvoltage protection of the load is provided by the "crowbar" circuit.

Since direct-conversion receivers like the one in the PM-3 are prone to picking up hum from an ac power supply, 0.01-μF capacitors were inserted parallel to each rectifier diode. The addition of these capacitors to the rectifying portion of the supply eliminated virtually all ac hum from the audio output of the PM-3.[2]

The Clocks

The digital-clock circuits used in this project were the MA1008A (National MM5385 12-hour-format chip) and the MA1008D (National MM5386 24-hour-format chip). Both clock chips were purchased new (close-out specials from Digital Research Parts) for under ten dollars for the pair. They came ready to use and required only a 12-V, 1.2-A transformer (which powered both chips) and momentary SPST switches (for setting the clocks) to be put into operation.

These chips were purchased in 1980, so their current availability and price may be different. However, there are a number of other parts-supply sources offering similar clock chips at very reasonable prices.[3] Flea markets and ham conventions are other possible sources.

The Callsign

The basic idea for the callsign came from the Heathkit SB-104 I once owned back in the pre-neighbor days. The lighted callsign in that rig consists of peel-and-stick letter blocks mounted on a transparent panel behind a red plexiglas™ filter. Each block has a black opaque background except for the outline of the letter which is clear to allow light to pass through when the panel light is turned on. It's a nice effect, and to my knowledge is a feature found only on the SB-104.

A 2″ × 1/2″ piece of window glass was obtained from the local hardware store as scrap. A dry transfer press-on letter set (#M12

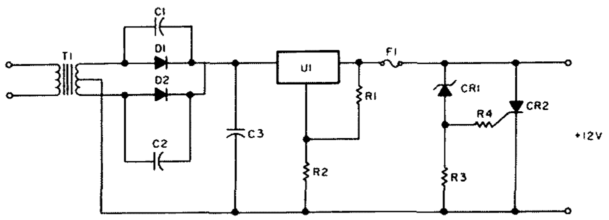

Fig. 1. Power supply schematic.

made by the C-Thru Ruler Co., Bloomfield, Connecticut, obtainable from stationery or art supply stores) was used to apply the call letters to the glass. The call letters were centered in both directions on the glass strip. Black enamel paint (obtainable at hobby stores selling modeling supplies) was applied to the glass surface using a fine-tipped brush. All of the glass surface surrounding the outlines of the letters was painted black. Two or three coats were necessary to ensure that no light could pass through the glass except through the letter outlines. By holding the glass up to a strong light after each coat of paint had dried, it was possible to see if a sufficient amount of paint had been applied to block out stray light.

A plastic 35mm film canister was used as the callsign housing. The end of the plastic film can was removed with a razor blade. A circumferential strip of about ¾ inch was removed lengthwise from the plastic can creating an incomplete cylinder. The end cap from this can and the end cap from another film can were fitted to the tube. The caps were then cut flush with tube edges.

Next, slits were cut in the end caps corresponding to the width and thickness of the glass strip. Illumination of the callsign was achieved by three 12-V bulbs (Radio Shack 272-1141) which were mounted equally spaced along the bottom surface of the tube. Holes were punched in the tube and the bulbs were snug-fitted. (Three small bulbs were used rather than a single, larger bulb in order to ensure even illumination of the callsign and to ensure that the bulbs remained hidden from view.)

A small piece of white poster paper was cut and wrapped along the inside wall of the tube. This white background served as a reflector to aid in achieving even illumination. The whole assembly was put together by sliding the glass strip through the slit in one end cap, snapping the end cap/glass strip into one end of the plastic tube and then fitting the other end cap to the tube. Photo B illustrates the stages in constructing the callsign housing.

The Enclosure

The enclosure used in this project was a Ten-Tec Model MG-10 ($4\frac{3}{16}$"H × $9\frac{15}{16}$"W × $6\frac{5}{16}$"D) obtained at a flea market. Any type of metal cabinet with similar dimensions would do equally as well. The cutouts for the clocks and the callsign light were done using square Greenlee tools. The edges of the resulting holes were rounded with a file. In order to eliminate unsightly clock-chip mounting screws from protruding on the front panel, flathead machine screws were epoxied to the inside surface of the cabinet. Finally, press-on lettering was used for the various labels. Photo C shows how the clocks, power supply, and callsign were mounted in the enclosure.

The finished product proved to be a handsome and useful addition to the station. Low cost and construction simplicity are two of the most attractive features of this project. ■

The Magical Audio Filter

A variable-frequency notch filter plus a peaking circuit will do wonders for your reception. And this project will almost build itself.

Audio filtering is a well-known process for improving receiver selectivity and many articles have been written on the subject. Because I have been in the process of building a direct-conversion receiver, I have been most interested in the subject. However, in order to further improve the receiver, I wanted more than the usual passband type of filter. Since one of the receiver modes is CW, I wanted a notch filter with a variable frequency and a variable-frequency peaking circuit. The notch filter could also be used on SSB reception to reject heterodynes from AM stations. Some of the requirements that I wanted for the notch filter were:

- a high Q (so the bandwidth at the 3-dB point of the notch frequency was approximately 200 Hz with a rejection of greater than 20 dB)
- the capability of shifting the notch frequency from 500 to 3 kHz
- a minimum number of parts.

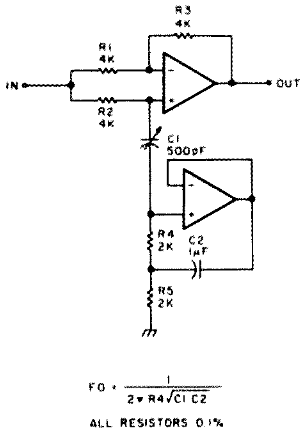

Fig. 1. Original circuit.

The Frequency-Notching Circuit

Most articles I'd seen on this subject showed at least three or four operational amplifiers plus a multitude of resistors and capacitors and therefore did not satisfy my third requirement.

One day, I accidentally ran across a number of circuits in a *National Semiconductor Linear Applications Manual.*[1] The circuit that interested me the most was the one providing variable frequency-notching using a variable capacitor. This circuit was constructed on a proto board and performed quite well, but the frequency range was limited by the maximum value of the capacitor. The basic circuit is shown in Fig. 1. The major drawback of this circuit was the large physical size of the capacitor as compared with the rest of the circuit.

Looking at the formula for the notch frequency (Fig. 1), one can see that the frequency is a function of R4, C1, and C2. The frequency varies directly as R4 and by the square root of C1 and

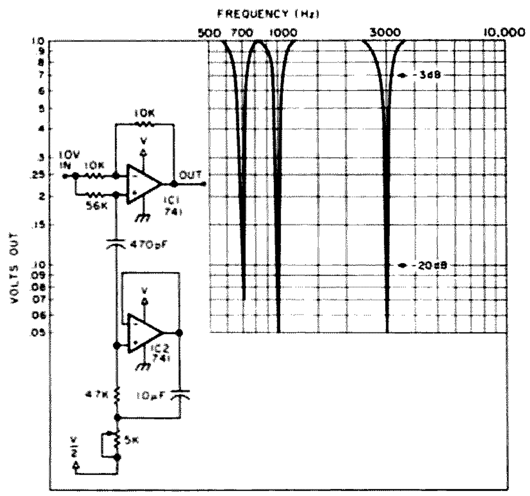

Fig. 2. Notch circuit.

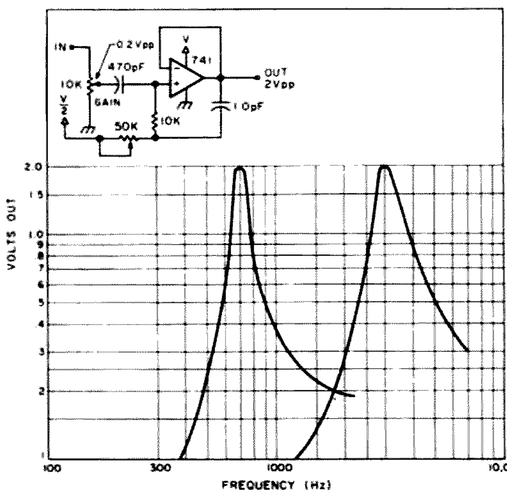

Fig. 3. Peaking circuit.

C2. Thus, if the resistor is doubled in value, the frequency doubles. Doubling the capacitors only gives 1.4 times the change. I decided to build the circuit with R4 variable and again results were very good. The frequency-range requirements were met and the rejection was greater than 20 dB. It did have one problem that was also experienced with the variable-capacitor circuit. In order to achieve maximum rejection at the high end vs. the low end, R3 had to be varied. Experimenting further, I found that if R5 were varied and R3 and R4 were properly chosen, only one control was necessary. Almost equal rejection could then be achieved across the whole range. A typical response is shown in Fig. 2.

The Peaking Circuit

Since the above circuit was rather novel (there is no signal inversion from input to output at the off null point), I started to look at voltages at various points with an oscilloscope. To my amazement, I found that when the output was going to null on IC1, the output was peaking on IC2. Eureka!—Here was the second circuit I was looking for. To accomplish peaking, only IC2 was needed. This circuit was constructed and the results are shown in Fig. 3. R_{in} is necessary to prevent saturation of the amplifier. The gain of this stage is about 10—therefore the input must be less than 0.5 volts. The power supply used was plus and minus 8 volts to be equivalent to the supply to be used in the final construction.

It will be noticed that there is an additional resistor that can be switched in or out in the final circuit. When the resistor is in, the peak is broadened and the circuit can be used on AM or SSB to modify the speech characteristics of the transmitted signal being received. It can reduce the low frequencies and accentuate the frequencies that transmit the spectrum that contains the most intelligence. It also reduces higher frequencies, thereby reducing background noise.

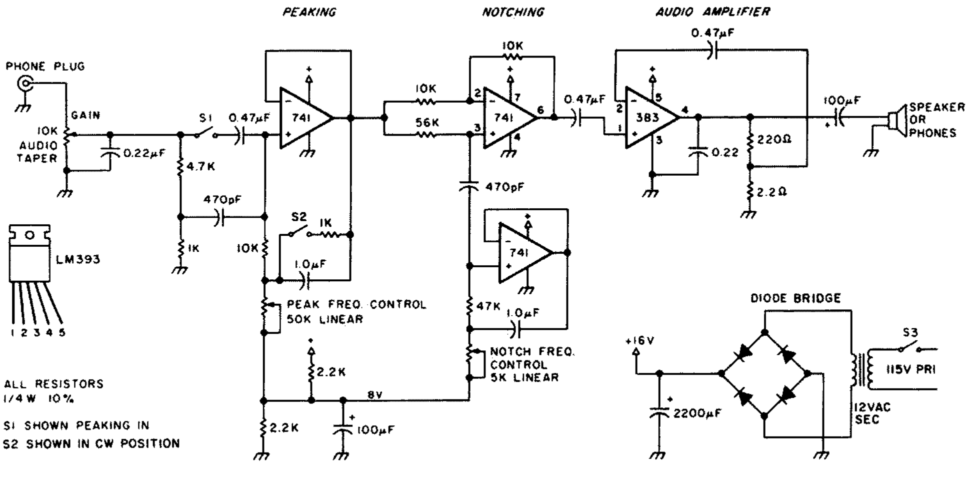

Fig. 4.

Combination Notch and Peaking Circuit

Fig. 4 shows the final circuit combining the two circuits. The circuit was constructed on a perfboard using wire-wrap sockets. The perfboard is mounted in a Radio Shack box with 1-inch spacers. Both the LM383 and the transformer are mounted to the box. One note of caution—the 0.22-uF capacitor on the output to ground on the LM383 should be mounted on the device terminals. The input cable, the output jack, and the 115-V-ac input all come in on one end of the box and the potentiometers mount on top.

For some reason, not many articles ever use perfboards and wire-wrap sockets. PC boards should be used for rf work, but the perfboard does very well for audio frequencies. The nice thing about wire-wrap circuits is that if you make a mistake, it can be corrected or modified easily. The following are some hints on building with a perfboard and wire-wrap sockets.

	Misc. hardware	

1. Make a Xerox® copy of the schematic; every time you put in a wire, mark it down. This is especially helpful should you put the project away and come back to it later.

2. Using a marking pen on the wire side of the board, indicate which pin is #1 for the IC sockets. Remember that the numbering on the wire side is opposite to that on top.

3. I use model-airplane cement to hold the IC sockets in place. If you want to reuse the perfboard, this type of glue allows the socket to be easily removed.

10816 Northridge Square • Cupertino, CA 95014
(408) 749-8330 ✓124

Clean the board with acetone when the sockets are removed.

4. It is also helpful to use different colors of wire for different parts of the circuitry.

5. Push-in teminals (Radio Shack #270-1392) are used to mount the resistors and capacitors. The wire-wrap wires are soldered to these terminals on the wire side of the board. (A special tool is available to insert these terminals but is not available from Radio Shack. Long-nose pliers can be used but are nowhere near as satisfactory as the tool.)

6. Mount the components when the push-in terminals are in place so as not to lose track of which terminal goes with which component.

7. Wire-wrapping is done with a manual tool to conveniently allow interchanging of wire colors. If you have never used a wire-wrap tool, the operation is very simple. In learning, the best way is to measure the distance between the two points to be wired and add 1¼ inch if wire-wrap to wire-wrap, add 7/8 inch for wire-wrap to teminal, and add ½ inch for terminal to terminal. For good measure, add on about ½ inch so the wire will not be too tight. Strip both ends 5/8 inch for wire-wrapping and ¼ inch for terminals. Stripping is done with a special tool provided with the wire-wrap tool. The bare wire is inserted into the end of the wire-wrap tool with the wire entering the smallest hole on the end of the tool. Place the tool over the terminal post to be wrapped and rotate the tool in a clockwise direction for about ten turns. The connection is now made. If you make a mistake, a tool is available to rotate in the opposite direction to remove the wire.

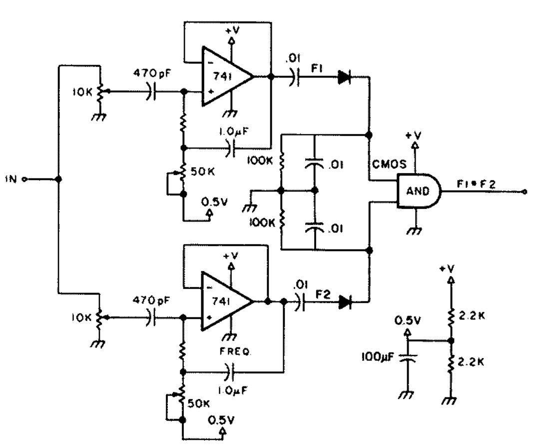

Fig. 5. Another application for peaking-circuit decoder.

Circuit Operation

When the project is finished, the input cable can be plugged into the phone jack of any receiver and the output to either a speaker or headphones. Set S1, the peaking-circuit switch, to OUT. Tune in a CW signal and adjust the signal frequency to give about an 800-Hz tone. Throw S1 to IN and turn the peaking control to a point where the maximum audio is heard. The first thing you will notice with the peaking switch in is the reduction in noise. As you approach the peaking point, the signal will increase greatly in volume. Of course, if some other frequency suits you better than 800 Hz, that is the listener's choice.

The next thing to check is the notch filter. With the 800-Hz signal coming in, adjust the notch control to a point where the signal drops in volume. On some CW signals with key clicks and thumps, the 800-Hz signal will drop out but the clicks and thumps will still be there. I have found that it is easier to remove a heterodyne with the peaking circuit out; then bring in the peaking circuit, producing an even greater reduction in the interfering signal. When the notch circuit is not used, the pot should be set to the low-frequency end.

Frequency-Selection Circuit

Another circuit is shown in Fig. 5. Although I have not tried this circuit, it could be of interest. I have tried LM567s in frequency-selective circuits, but noise spikes seem to get through, creating an unwanted output signal. A case in point is my garage-door opener. This unit had a vibrating-reed type of frequency detector and I replaced it with a pair of LM567s. Every once in awhile the door will open without a command due to noise. After I finish this project, reworking the opener will be my next project.

Conclusion

The peaking/notching circuit should be a worthwhile addition to any receiver for a parts cost of about $35 excluding the wire-wrap tool and wire that can be used on many other projects. It is a simple but effective way to gain a bit more selectivity that should improve any old receiver and maybe some of the newer ones.

A list of parts is given with all but one being available from Radio Shack. Of course, most hams will have many of these parts available in their junk boxes, bringing the overall cost down. ■

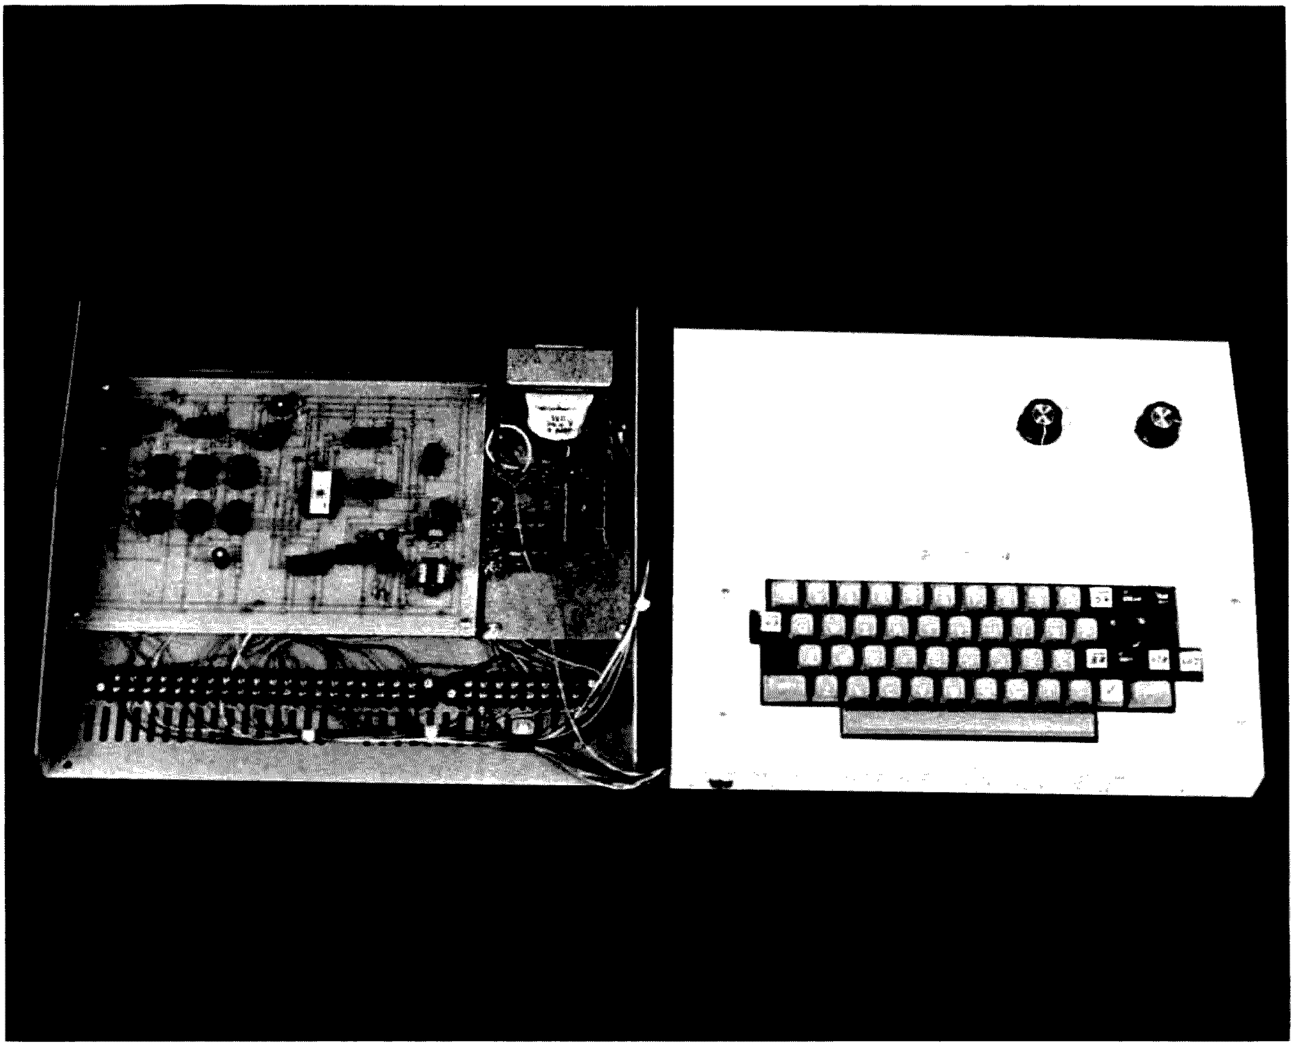
Keyboard Your Way to Happiness

If happiness is perfect Morse, then this project is pure heaven. Special construction tips make putting it together as much fun as using it.



Sending Morse code accurately and at relatively high speeds has been made possible with the advent of the Morse keyboard. Perfect Morse code with perfect spacing is possible with a Morse keyboard with a buffer memory. Many of the physical limitations that are encountered while using other manual keying methods have been overcome by the Morse keyboard. The Morse keyboard has become a valuable instrument for sending Morse code and will continue to play an important role in communications.

This article will describe a Morse keyboard with a 192-character buffer memory. It will send perfect Morse code with perfect spacing as long as the operator stays ahead of the outgoing code. If the Morse-code operator tends to fall behind, the spacing may become erratic, but the Morse code itself will not be affected.

The Morse keyboard is made up of an ASCII communications keyboard, a buffer memory, and an ASCII6-to-Morse converter. The 192-character buffer memory allows the operator to type as many as 192 characters and word spaces ahead of the outgoing Morse code. An experienced operator may type ahead and then take time out to fill out the log book while the Morse code is being sent out.

The Morse keyboard may also be used as a code-practice device, allowing a person who does not already know the Morse code to send perfect code to a student who is learning the code.

I have been using the Morse keyboard at speeds of up to 40 words per minute on the ham bands and have checked the Morse-code waveforms on an oscilloscope at much higher speeds. The waveforms indicate that the Morse keyboard is working satisfactorily at speeds well over 80 words per minute.

ASCII Keyboard

The ASCII keyboard is an ASR-33, 53-key, data-communications type of keyboard. There are several manufacturers who make this type of keyboard. A microcomputer may also be used as an ASCII signal source.

I am using 26 letters, 10 numbers, 4 punctuation marks, and the special Morse-code characters AS (wait), BK (break), AR (end of message), and SK (end of transmission) for a total of 44 Morse-code characters. All of the characters for this particular Morse keyboard are arranged for the lowercase position on the keyboard and some of the keytops have been rearranged so that all of the characters are readily available without having to use the keyboard shift keys. The question mark, which is normally an uppercase character, has been moved to a lowercase position on the keyboard. Some of the special Morse-code characters do not have an ASCII equivalent, but have been substituted for other unused characters.

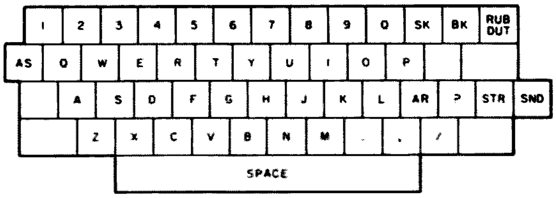


Fig. 1. The N7AGK ASR-33 Morse keyboard layout

A strobe or keypunch pulse is supplied by the ASCII keyboard each time a character key is pressed and is used to enter data into the buffer memory. This arrangement allows the operator to type at an uneven rate and to enter data into the buffer memory whenever a key is pressed.

Fig. 1 shows the keyboard layout for the Morse keyboard. Most ASCII keyboards have been designed so that the keytops may be easily removed and placed in a different location on the keyboard. Keytops are available that have special titles.

Buffer Memory

Fig. 2 is a schematic of the buffer memory. The buffer memory is a type of digital storage system which allows the Morse-keyboard operator to enter data at different rates or to store data in the buffer memory until needed. Data will remain stored in the buffer memory as long as power to the buffer memory is not interrupted.

The 192-character buffer memory is made up of 3 pairs of 3341 first-in/first-out shift registers. Each pair will handle 64 ASCII6 characters. (The Morse keyboard uses only 6 bits of the ASCII data from the ASCII keyboard.) Each 3341 FIFO shift register handles 4 bits of information in a 64-by-4 configuration. The buffer memory accepts parallel

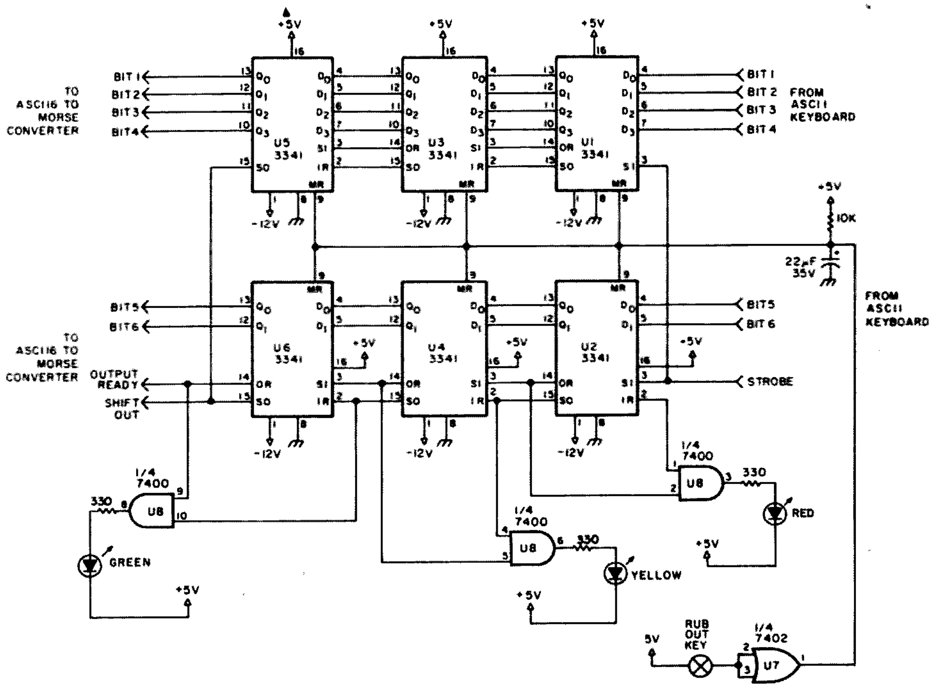

Fig. 2. 192-character buffer memory.

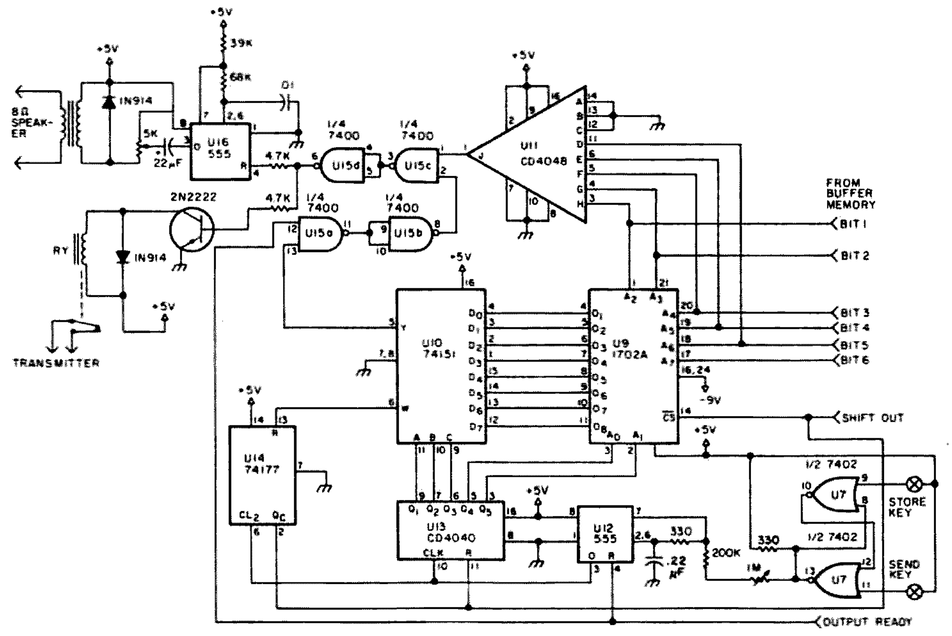

Fig. 3. ASCII6-to-Morse converter.

data only from the ASCII keyboard.

The 3341 FIFO has separate input and output data terminals and has separate input and output clock circuits that can operate at different clock rates. The input clock pulse is called a shift-in pulse and the output clock pulse is called a shift-out pulse. The shift-in pulse is the ASCII keyboard strobe or keypunch pulse which allows data to be entered into the buffer memory whenever a key is pressed. The shift-out pulse is supplied by a Morse-code character-space circuit in the ASCII6-to-Morse converter and will be described in detail later in the article.

The buffer memory may be thought of as a pipe which will hold up to 192 marbles. The shift-in rate is the rate at which marbles are placed in the pipe. The shift-out rate is the rate at which marbles are removed from the pipe. If marbles are not added to the pipe, but are removed, the pipe will become empty after a period of time. If marbles are entered and removed from the pipe at the same time and at the correct rates, a continual supply of marbles will be present in the pipe.

Too short a buffer memory may require a Morse-code operator to stop and wait during an inconvenient part of the Morse-code transmission or may cause the operator to stop and wait in the middle of a sentence, thereby interrupting his chain of thought. A large buffer memory will allow the Morse-code operator to type in a larger portion of a message without having to stop and wait as often.

The buffer memory has 3 functions available which are controlled by 3 function keys on the ASCII keyboard. A Store key allows the operator to enter data into the buffer memory without data being removed. A Send key allows the operator to remove data from the buffer memory. Data may be removed from the buffer memory while data is being entered. A Rub Out key is used as a master reset for the buffer memory and erases any information stored in the buffer memory when pressed.

The function keys supply +5 V when pressed and supply zero or ground potential when not pressed. The Send key and Store key supply signals to a simple flip-flop circuit which ensures that either one or the other function is operating at any given time, but that they are not operating simultaneously. The simple flip-flop circuit is half of U7 or 2 NOR gates of a quad 7402 NOR gate. When the Store function is operating, the ASCII6-to-Morse converter clock generator, U12, is shut off. During this function, data is prevented from leaving the buffer memory.

During the Send mode, the clock generator is allowed to operate, thus allowing data to be shifted out of the buffer memory.

There is an LED indicator light for each pair of 3341 FIFO shift registers. These indicator lights are used as warning or indicator lights for the convenience of the Morse-keyboard operator. I chose a green LED for the first pair of 3341s, a yellow LED for the second pair, and a red LED for the third pair. The red LED blinks whenever a character is typed and acts as a warning that the buffer memory is close to being full. The green LED is lit when there are between one and 64 characters in the buffer memory. The yellow LED is lit when there are between 64 and 128 characters in the buffer memory. The red LED is lit when there are between 128 and 192 characters in the buffer memory. If the buffer memory is empty, none of the LED indicator lights will be lit. The LED indicator lights are positioned on the Morse keyboard so that they may be easily observed by the Morse-keyboard operator.

Fig. 4. Flow of data from the ASCII keyboard to the 74151 demultiplexer output.

The Rub Out key is a function of the ASCII keyboard and is used when the Morse-keyboard operator desires to erase all of the information that is in the buffer memory. One-fourth of a quad 7402 NOR gate is used as an inverter. The master-reset voltage is zero. The master-reset line is held at +5 V by a 10k resistor and will not reset until a zero-volt level is received from the 7402 NOR gate inverter.

A 22-microfarad electrolytic capacitor from the master-reset line to ground ensures that the master reset has reset the buffer memory when the Morse keyboard is first turned on. If the capacitor was not there, the buffer memory could contain some unwanted information when the power is first turned on.

ASCII6-to-Morse Converter

The ASCII6-to-Morse converter portion of the Morse keyboard (Fig. 3) is made up of circuitry that converts the ASCII6 data from the buffer memory to usable Morse code. The ASCII6-to-Morse converter contains a memory circuit that is used as a code converter, a space-bar-operated word-space circuit, an automatic character-space circuit, a clock generator, a divider circuit, a sidetone generator, and output circuitry for operating the keying relay.

1702A Memory Circuit

A 1702A EPROM (erasable programmable memory), U9, is used as an ASCII6-to-Morse converter and converts the data from the buffer memory to Morse code. The 1702A has a total of 2048 storage locations and has an overall configuration of 256 by 8. This means that there are 256 address locations with 8 parallel outputs for each address location.

Signal source		Address Inputs	
	Q1	A	74151
CD4040	Q2	B	Demultiplexer
Address	Q3	C	
Divider	Q4	A0	
	Q5	A1	
	Bit 1	A2	
ASCII6	2	A3	1702A
From	3	A4	Memory circuit
Buffer	4	A5	
Memory	5	A6	
	6	A7	

Table 1. Address and divider information.

I have chosen 4 groups of 8 outputs for a total of 32 storage locations for each Morse-code character. This arrangement allows room for up to 62 Morse-code characters and a word space in the 1702A memory circuit.

The ASCII6 data addresses the 1702A for the desired Morse-code character. (The ASCII keyboard will supply 8 bits of information for each character, but with the Morse keyboard, only the ASCII6 or bits 1 through 6 are used.) The ASCII6 data addresses the 1702A memory circuit so that a respective 32-baud storage section of the memory circuit is selected for the desired character.

The 1702A memory circuit is programmed so that each storage location is equivalent to one baud. The Morse-code characters are broken down so that a dot is one baud in length and is programmed into the memory circuit as a 1; a dash is 3 bauds in length and is programmed as 3 ones in a row. A character space is 3 zeroes in a row. A space between dots and dashes is 1 zero. A word space is 7 zeroes in a row and will be handled in a special way in the ASCII6-to-Morse converter circuitry. (The 1702A memory circuit normally contains all zeroes until programmed.)

None of the Morse-code characters uses all of the 32 bauds or 32 storage locations assigned to them. The shortest Morse-code character, the letter E, uses 1 baud for the code character plus 3 bauds for the character space for a total of 4 bauds. The longest Morse-code character used in the Morse keyboard is the number zero. It uses 19 bauds or storage locations for the Morse-code character plus 3 bauds for the character space for a total of 22 bauds or storage locations in the memory circuit.

74151 Demultiplexer

The output of the 1702A memory circuit is in an 8-bit parallel form and must be converted to a serial form in order to key a transmitter properly. The parallel information from the 1702A memory circuit is converted to serial information with a 74151 demultiplexer integrated circuit, U10. The 74151 demultiplexer uses 3 binary address signals to assist in converting from the 8 parallel inputs to the serial outputs. Output Y is inverted.

Fig. 4 shows a flow of the data from the ASCII keyboard to the output of the 74151 demultiplexer. Some examples of code characters are shown in the buffer memory and at the output of the 1702A and 74151.

Character-Space and Shift-Out-Pulse Circuit

The ASCII6-to-Morse converter circuitry is designed so that it will accept the Morse-code information for each Morse-code character plus 3 zeroes at the end of the character for a character space. If there are more than 3 zeroes at the end of a character, the character-space circuitry will accept the first 3 zeroes and then proceed to the next Morse-code character, ignoring the remaining zeroes. In the memory circuit, a letter E, for example, will be followed by 31 zeroes, but the character-space circuitry will accept only the first 3 and ignore the remaining 28 zeroes.

The 74177 character-space-divider circuit, U14, is connected so that it will accept 3 zeroes in a row and then supply a very short duration shift-out pulse to the buffer memory. The shift-out pulse initiates the start of the next Morse-code character or word space and also resets the 1702A memory circuit and a CD4040 address-divider circuit, U13. When the memory circuit and divider circuit have been reset, the ASCII6-to-Morse converter circuitry is ready to accept the next ASCII6 character from the buffer memory. The reset and shift-out pulse from the 74177 character-space divider is extremely short in duration. It will not interfere with the timing of the first baud of the next Morse-code character.

The character-space divider is reset every time a dot or dash is received from the 74151 demultiplexer. The Morse-keyboard clock-generator signal is fed into the input of the character-space divider. When 3 zeroes in a row are present at the reset input of the character-space circuit, a pulse is then present at the divider output, Qc, which is the buffer-memory shift-out pulse and also the reset pulse for the CD4040 address divider and the 1702A memory circuit. As soon as the shift-out pulse is generated, a new ASCII6 character is shifted out of the buffer memory and presented to the 1702A memory cir-

Table 2. 1702A programming truth table.

cuit which in turn is routed through the 74151 as a Morse-code character and resets the 74177 character-space divider. The 74177 character-space divider does not have a chance to generate a very long duration pulse because of the quick action of the 1702A memory circuit and the 74151 demultiplexer.

Clock Generator and Address Divider

The ASCII6-to-Morse converter uses a 555 timer as a clock generator (U12). The clock generator operates at 2 times the bit rate of the Morse code. The clock generator is varied in frequency in order to vary the speed of the outgoing Morse code. The clock-generator signal is fed to the 74177 character-space divider and a CD4040 binary address divider, U13.

The ASCII6 data from the buffer memory addresses the 1702A memory circuit for the respective 32-baud storage section assigned the Morse-code character. However, additional addressing is needed to break down the Morse-code signals to the 8 parallel outputs of the 1702A memory circuit and to further break down the signal to a serial form in the 74151 demultiplexer. The additional binary addressing is supplied by the CD4040 divider circuit. Table 1 shows a breakdown of the signal sources and address locations. Q1, Q2, and Q3 are binary signals used to address the 74151 demultiplexer; U10 and Q4 and Q5 outputs are address signals for the 1702A memory circuit.

1702A Programming Information

Table 2 is the truth table for programming the 1702A EPROM. The address and output information for the 1702A memory circuit is shown in binary form for simplicity. There are 8 address bits. The first 6 address bits are the ASCII6 data and the last 2 bits are needed to break down the information in the 32-baud storage sections into the 8 parallel outputs of the 1702A memory circuit. Of the 8 address bits, the first 6 bits reading from left to right are bit 6, bit 5, bit 4, bit 3, bit 2, and bit 1 of the ASCII6 data. The 7th address bit, reading from left to right, corresponds to the Q5 output of the CD4040 address divider and the 8th bit corresponds to Q4. The address inputs of the 1702A memory circuit, reading from left to right, are A7, A6, A5, A4, A3, A2, A1, and A0.

The address for the letter A will be 00000100. The letter B, which is more than 8 bauds in length, will have 2 addresses. They are 00001000 and 00001001. Note that bit 8 of the address has changed. The output programming of the 1702A memory circuit will be 11101010 and 10000000. Note that the first 3 bauds are a dash. Bauds 5, 7, and 1 of the next group are dots. They make up the dash and 3 dots of the letter B. Longer Morse-code characters such as the number zero will take 3 sets of addresses for the programming of the memory circuit.

The 1702A memory circuit is normally all zeroes before programming. The memory circuit need only be programmed for 1s. A special programmer must be used with the 1702A EPROM and the memory circuit may be erased with ultraviolet light and programmed again if desired.

CD4048 Word-Space Gate

The Morse keyboard uses an ASCII-keyboard space-bar-operated word space that is handled in much the same way as a regular Morse-code character. The one big difference is that it is silent at the output of the Morse keyboard. The word space must be 7 bauds in length and must work correctly with the 74177 character-space divider.

The ASCII6 code for a word space is 100000. It is the only ASCII6 character that has zeroes for bit 5, bit 4, bit 3, bit 2, and bit 1. There is an ASCII6 blank that has all zeroes, but it is not used with the Morse keyboard. The 1702A programming address for the word space is 10000000. An E is programmed into the 1702A for a word space and is shown as 10000000 also.

An 8-input expandable gate is used as the word-space gate and is connected as an 8-input OR gate. 3 of the inputs to the OR gate are grounded and the other 5 inputs are connected to bit 5, bit 4, bit 3, bit 2, and bit 1. If any input of the CD4048 OR gate is receiving a 1, the output will show a 1. If all of the inputs are zero, then the output will be zero. If there is a zero at the output of the CD4048

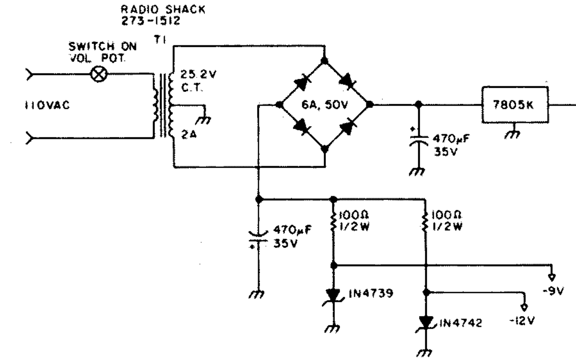

Fig. 5. Power supply schematic.

word-space OR gate, the output circuitry of the ASCII6-to-Morse converter will be silenced. There will be a silent E present at the output of the Morse keyboard which is 4 bauds long. When added to the 3 zeroes of the previous character space, there will be a total of 7 silent bauds, which is the length of a word space. Since the word space is treated much the same as an ASCII6 character, it will be treated like one in the buffer memory.

Output Gates

In the output circuitry of the ASCII6-to-Morse converter, there are 4 NAND gates, designated U15A, U15B, U15C, and U15D. U15B and U15D are connected as inverters.

U15A is connected as a NAND gate and combines the output-ready signal from the buffer memory and the serial-output signal from the 74151 demultiplexer, U10. The output-ready signal also resets the 555 clock generator, U12. The output-ready signal is used to synchronize the buffer-memory output signals and the clock generator. Without the synchronizing of the signals, it would be possible to miss a part of the first baud of the Morse-code character.

U15C is also connected as a NAND gate and combines the output of the word-space gate with the signal from U15B and determines whether the output will be silenced for a word space or enabled for a regular Morse-code character.

U15D is an inverter and a buffer for the output signal.

Sidetone Generator

A 555 timer, U16, is connected as a sidetone generator for monitoring the outgoing Morse code. It generates an audio tone and is keyed by the signal from U15D. The sidetone generator has an output transformer with an output for an 8-Ohm speaker or 8-Ohm headphones. The frequency of the sidetone generator is approximately 800 Hertz. The sidetone generator has a volume control. The volume may be turned up when using a speaker and turned down if headphones are used. The 1N914 diode across the primary of the output transformer furnishes a more pleasant tone at the output of the sidetone generator.

Keying Relay

I am using a Radio Shack #275-215, double-pole double-throw miniature plug-in relay for the transmitter keying relay. It is a 5-volt relay with a 50-Ohm relay coil. I bent the relay contacts closer together to improve the response time of the relay. A 2N2222 transistor amplifier is used as a relay driver. The relay plugs into a regular 16-pin DIP socket.

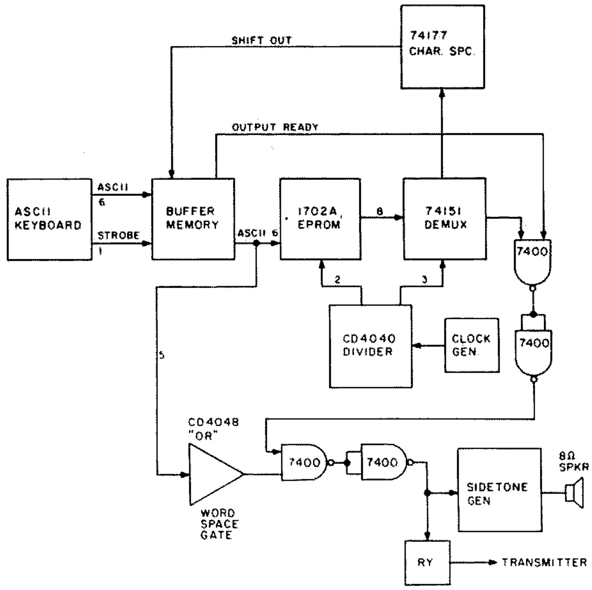

Fig. 6. N7AGK Morse keyboard block diagram.

Power Supply

Fig. 5 is a schematic of the Morse-keyboard power supply. It supplies 5 volts at approximately 1 Ampere, minus 9 volts at approximately 25 milliamperes and minus 12 volts at approximately 25 milliamperes. A Radio Shack #276-1363 power transformer is used for the low-voltage power source. The secondary winding of the transformer supplies 25.2 volts at 2 Amperes. A bridge rectifier is connected so that one side of the rectifier supplies the plus voltage in reference to the transformer center tap and the other side of the rectifier supplies a minus voltage in reference to the center tap. The plus side goes to a 5-volt regulator and the minus 9 volts and the minus 12 volts are taken from zener-diode circuits. The transformer center tap is at ground potential. The 1702A memory circuit uses plus 5 volts and minus 9 volts. The 3341 first-in/first-out shift register uses plus 5 volts and minus 12 volts. All of the other circuits just require plus 5 volts. A good heat sink must be used with the 5-volt regulator to prevent overheating of the regulator.

Operating Instructions

The Morse keyboard has been designed to send perfect Morse code with perfect spacing. It has a buffer memory which allows the Morse-code operator to type up to 192 characters ahead of the outgoing Morse code. The buffer memory will store the characters until they are needed. If the operator presses the Store key, he may store a small message and then send it out when the Send key is pressed. The message will be stored in the buffer memory as long as power is supplied to the Morse keyboard. I have stored a message overnight and then listened to it in the morning when I pressed the Send key.

The buffer memory also allows the Morse-code operator to type at an uneven rate and to stop at certain intervals if desired. If the Morse-code operator pauses too long, he may find that the buffer memory has emptied of information and there will be uneven spacing of the Morse-code characters until he has gained a head start on the outgoing Morse code again.

A message or transmis-

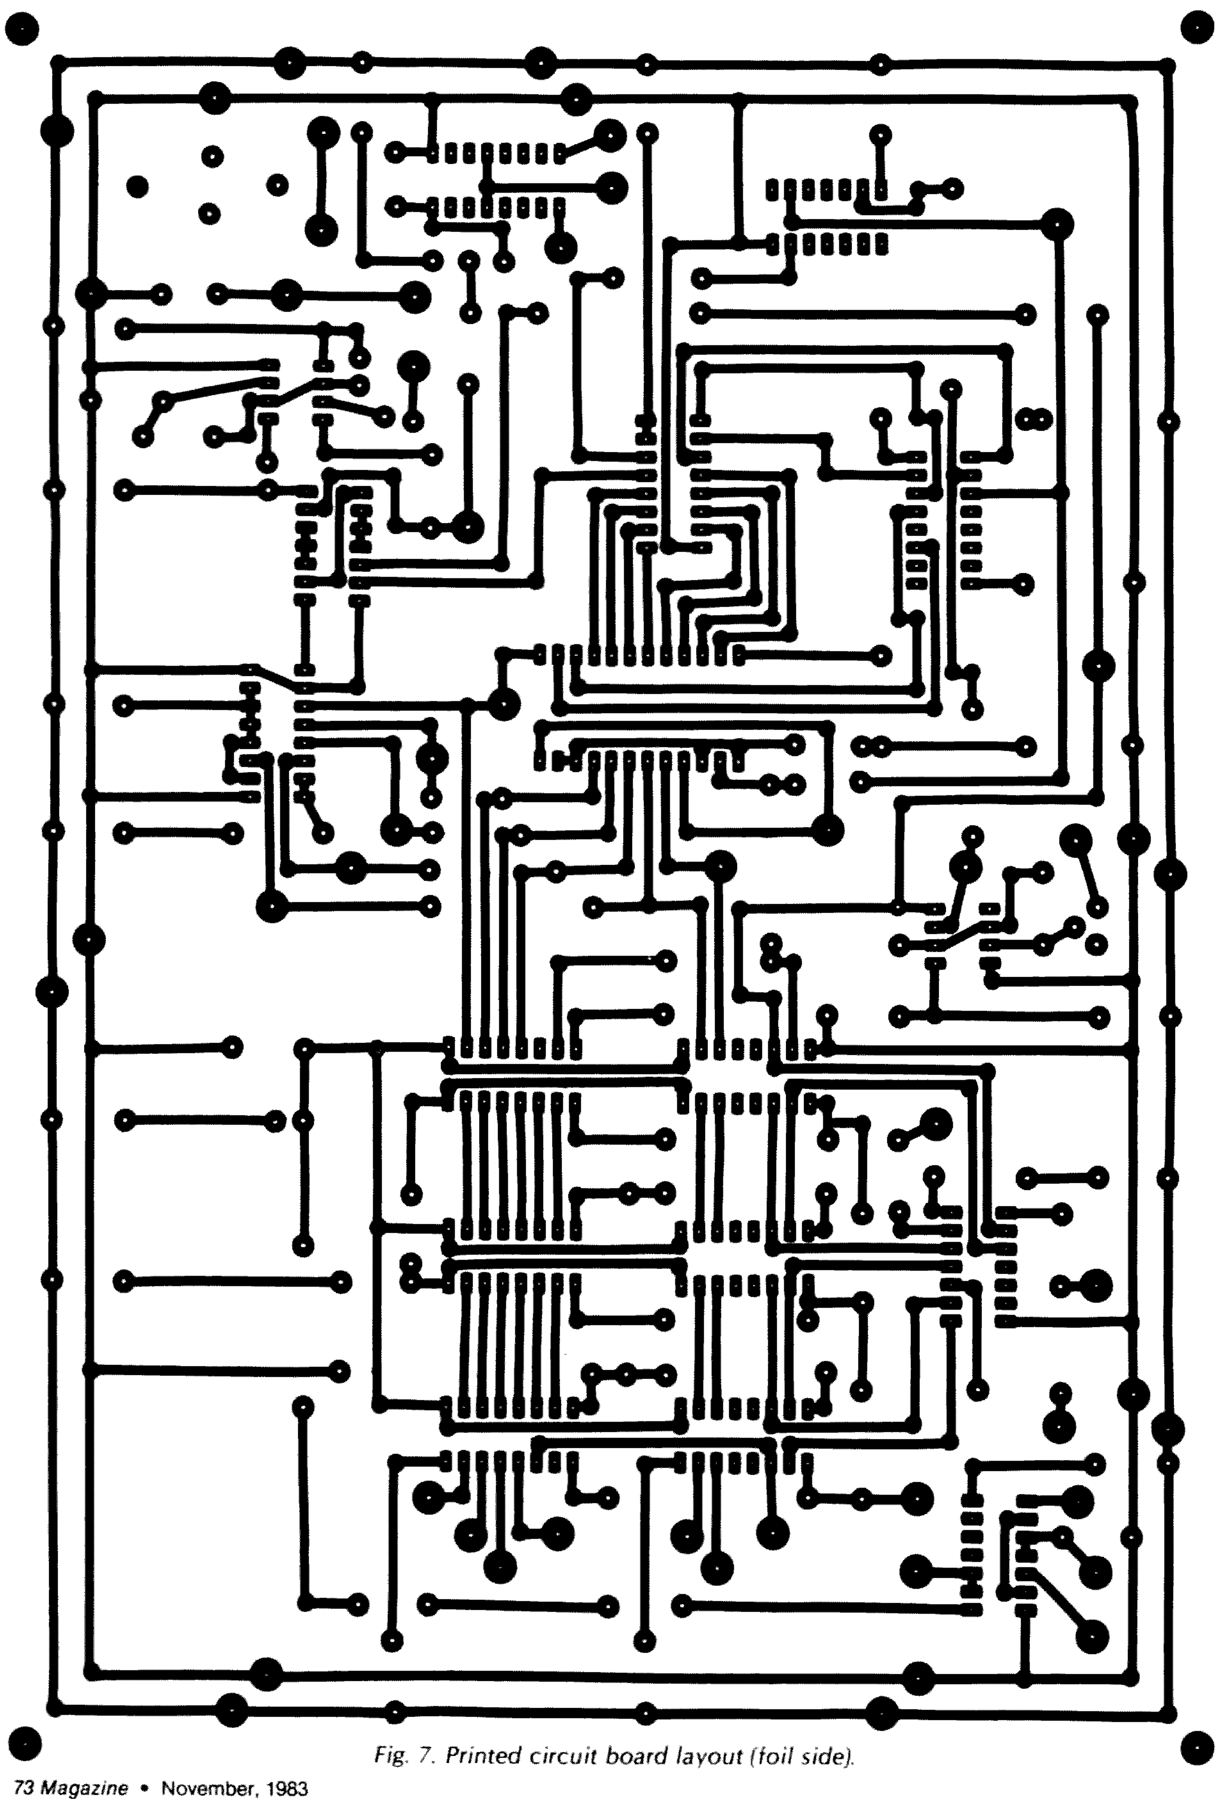

Fig. 7. Printed circuit board layout (foil side).

sion should always be started with at least one word space. If the operator desires to get a good head start on the Morse keyboard, he may need to press several word spaces in rapid succession. If the Morse-code operator desires to store a message, he should start with a word space. If a message is started with a character instead of a word space while in the Store mode, the operator will hear a steady tone. The steady tone may be used to tune the transmitter. To stop the steady tone, press the Rub Out key or the Send key.

Sometimes it is convenient to type part of a message into the buffer memory while receiving Morse code from the other station being worked.

At first, some people may become confused when hearing the Morse code going out after they had previously typed it into the Morse keyboard. The Morse keyboard has a sidetone generator for monitoring the outgoing Morse code, but not for monitoring the code before it enters the buffer memory. It would be almost impossible to monitor the Morse code as it is being typed into the Morse keyboard. It would not be practical to use the extra circuitry that it would require to do it. After a little practice, the Morse-code operator will find that it is very easy to type a message correctly while monitoring

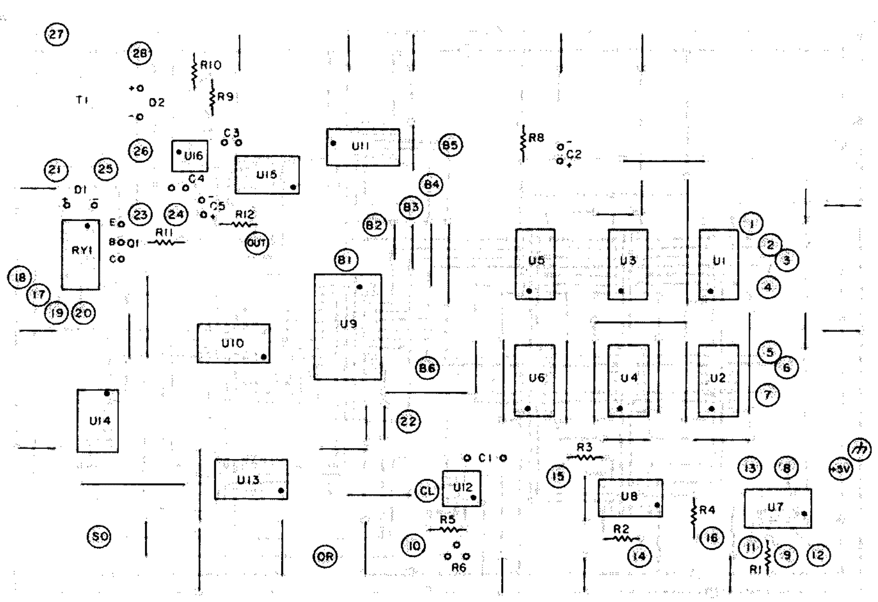

Fig. 8. Component layout.

PRINTED CIRCUIT BOARD ASSEMBLY

The printed circuit for the N7AGK Morse keyboard has been laid out on a 7-inch by 10-inch single-sided printed circuit board. The printed circuit layout has been especially arranged for ease of assembly. All external wiring connections to the printed circuit are made with push-in terminals.

All jumpers, sockets, terminals, and parts are shown on the printed circuit parts drawing. The drawing shows the parts side of the printed circuit board which is opposite the foil side.

The jumpers should be installed and soldered first. The jumper wire is pre-tinned, 24-gauge, copper bus wire. The jumper wires are shown as dark lines on the parts-side printed circuit drawing.

The resistors and diodes should be installed and soldered next.

Sockets are recommended for the integrated circuits and the keying relay. The sockets must be installed so that the notch end corresponds to the black dot on the parts-side printed circuit drawing. Extreme care must be taken when soldering sockets to prevent bridging across of the solder. A low-power solder iron and good quality, small-diameter, rosin-core solder is recommended. Do not overheat the solder connections and do not use excessive amounts of solder for the solder connections.

When installing C2 and C5, be sure to watch for correct polarity.

Install the 2N2222 keying driver transistor with approximately 3/8 inch of the transistor lead remaining between the transistor and the solder connection. Be careful not to use excessive heat when soldering the transistor leads to the printed circuit.

The black lead of T1 is not used. It may be clipped off if desired.

Install the push-in terminals as shown on the printed circuit drawing. Install output transformer T1 and solder the leads to their respective push-in terminals as shown in Printed Circuit Board Terminal Connections for connections 25, 26, 27, and 28.

Install and solder C4, C3, C1, and R6. (This should complete the printed circuit board assembly.)

Check the assembled printed circuit board carefully before attempting to use the circuit board in your Morse keyboard.

PRINTED CIRCUIT BOARD TEST TERMINALS

B1, B2, B3, B4, B5, and B6 are the ASCII information bits coming from the output of the buffer memory and going into the 1702A EPROM, U9, and the CD4048 word-space OR gate, U11.

SO is the shift-out pulse line from the 74177 character-space divider, U14. The shift-out pulse initiates the presentation of the next ASCII6 character from the buffer memory. It may be used as an external sync trigger pulse when viewing the outgoing Morse code on an oscilloscope.

OR is an output-ready signal line from the buffer memory. It resets the clock generator and ensures that the outgoing Morse code is in sync with the clock generator.

CL is the clock-generator output. It has a pulse rate that is 2 times the baud rate of the outgoing Morse code.

OUT is the outgoing Morse-code test point.

The ground and +5-volt connections for the ASCII keyboard may be taken from the extra terminals shown at the right of the parts-side drawing.

PRINTED CIRCUIT BOARD TERMINAL CONNECTIONS

The N7AGK ASCII6-to-Morse converter printed circuit board uses small push-in terminals (Radio Shack 270-1394) for all external connections and test points. They are inserted from the parts side of the printed circuit board and soldered in place. When wiring to the printed circuit board, all connections should be made on the foil side.

Connections 1, 2, 3, 4, 5, and 6 are the ASCII6 bit connections from the ASCII keyboard. Bit 1 is pin 7 on the ASCII keyboard. Bit 2 is pin 6, bit 3 is pin 5, bit 4 is pin 4, bit 5 is pin 11, and bit 6 is pin 10. (See the Keytronic data sheets.)

Connection 7 is a strobe- or keypunch-pulse connection to the ASCII keyboard. It is connected to pin 12 on the ASCII keyboard.

Connection 8 is Rub Out and is connected to the Here Is key, pin K on the ASCII keyboard.

Connection 9 is to the speed potentiometer counterclockwise terminal (looking from the bottom).

Connection 10 is to the center terminal of the speed potentiometer.

Connection 11 is Store and is connected to the Rept key, pin H on the ASCII keyboard.

Connection 12 is Send and is connected to the Break key, pin J on the ASCII keyboard.

Connection 13 is −12 volts and comes from the power supply.

Connection 14 is a connection to the green LED buffer memory indicator light. The connection is made to the negative side or flatted side of the LED. The positive lead of the LED goes to +5 volts.

Connection 15 goes to the negative side of the yellow LED.

Connection 16 goes to the negative side of the red LED.

Connection 17 is +5 volts from the power supply.

Connection 18 is to ground.

Connections 19 and 20 are the relay contacts for keying the transmitter. Connection 19 goes to the ground connection of the keying jack at the rear of the Morse-keyboard cabinet and connection 20 goes to the other connection of the keying jack. The keying jack is a standard phone jack.

Connection 21 goes to the phone or speaker jack on the front of the Morse keyboard. The other connection is grounded.

Connection 22 is −9 volts from the power supply.

Connection 23 is the counterclockwise connection to the volume potentiometer (looking from the bottom).

Connection 24 is the center connection to the volume pot. The remaining connection on the volume pot goes to +5 volts.

Connection 25 is for the red wire from T1. Connection 26 is for the green wire from T1. Connection 27 is for the white wire from T1. Connection 28 is for the blue wire from T1.

the outgoing code. An error in typing is easily recognized by the Morse-code operator and may be corrected by hitting the word-space bar and then sending a question mark and then hitting the word-space bar again and then sending the word or characters again correctly.

The Morse keyboard is an excellent device for learning the Morse code or for increasing one's code speed. A portion of a Morse-code practice transmission may be copied on the Morse keyboard by pressing the Store key and copying the Morse code and then playing the Morse code back at a slower speed by adjusting the speed control and pressing the Send key. The Morse code is played back at a slower speed to check for accuracy of receiving the practice transmission.

Another person who does not know the Morse code himself may type characters into the Morse keyboard and send them at a speed that is comfortable for a person learning the Morse code. The Morse-code speed may be set for a certain speed and the characters spaced for several seconds if desired.

As the Morse-code learner becomes better at receiving the code, the spacing between characters may be gradually decreased until it becomes the normal character spacing. Another method of spacing is to use a word space or two in place of a character space and then add several word spaces in place of a normal word space to distinguish between words or groups of Morse-code characters.

The speed of the Morse keyboard may be set for a range of approximately 5 words per minute to over 70 words per minute. It is easy to stay ahead of the outgoing Morse code when operating at the slower speeds, but at the higher speeds it becomes increasingly more difficult to stay ahead. The Morse-code operator should never send out Morse code at a higher speed than he can copy comfortably unless he is using a video readout for monitoring the transmission. Even with a video readout it can be risky business when external interference prevents the video readout from receiving the Morse code correctly.

Typing will be no problem for the beginning operator as long as he is careful to type according to standard typing procedure. An operator should never type using the "hunt and peck" system because it will hinder him later when he desires to increase his Morse code and typing speed.

Most beginning Morse-code operators will find that it is usually easier to increase one's typing speed than it is to increase one's Morse-code speed. A beginner should endeavor to type faster than he normally can receive the Morse code in order to stay ahead of the outgoing Morse code when using the Morse keyboard. For instance, a Morse-keyboard operator who can send and receive code at 15 words per minute must be able to type faster to stay ahead of the outgoing Morse code. If he cannot type faster than the outgoing Morse code, he may have trouble when short Morse-code characters like E and I, etc., appear frequently in the message.

One of the principal advantages of the Morse keyboard is the ability to send perfect Morse code at higher speeds than is possible otherwise. Many Morse-code operators reach the limit of their code-sending abilities at approximately 30 words per minute. The Morse keyboard extends the range that the Morse-code operator may otherwise attain. The ability to send and receive Morse code more accurately and more easily is a decided advantage for the Morse-code operator.

Construction

The printed circuit board is a single-sided, 7-inch by 10-inch board that has been laid out for easy assembly and soldering. I spaced the layout so that none of the jumper connections or terminal connections is very close to any other one. The closest solder connections are for the integrated-circuit socket connections.

I have used push-in solder terminals for the connections to and from the printed circuit board and for some of the test terminals.

The photograph shows two Jones terminal strips for connections between the printed circuit board and other locations of the

Morse keyboard. These are not absolutely necessary and may be omitted. I have been using them for testing purposes.

The printed circuit board and the metal plate for the power supply are mounted on the bottom of the keyboard cabinet on metal standoffs. The wiring from the printed circuit board to other parts of the Morse keyboard is brought out from the bottom side or the foil side of the board.

Availability of Components

I will supply a drilled and etched printed circuit board for $25.00 postpaid in the US and Canada along with complete instructions for wiring and assembly. I will supply a programmed 1702A EPROM for $10.00 or program a reader-supplied 1702A EPROM for $6.00 postpaid.

I will supply a Keytronic model L1648, 53-key, ASR-33 data-communications ASCII keyboard with the proper keytops for $100 postpaid in either the US or Canada. The ASCII keyboard uses a capacitance-type keyswitch and has over a 100-million-keystroke reliability. The keyboard is fully assembled and has a rigid mounting frame and removable two-shot molded keytops. (A two-shot molded keytop is one that has the character molded within the keytop so that it will not wear off with continued use.) The ASCII keyboard is available with schematic and data sheets.

The Morse-keyboard cabinet is a 14-inch-wide by 11.3-inch-deep sloping panel keyboard cabinet manufactured by Hammond. The bottom portion is #1456 PL3 CBU and the matching top portion is #1456 PL3 PWH. It is the same keyboard cabinet as is shown in the photograph.

If the Morse-keyboard builder already has an ASCII keyboard, he may use it with the Morse keyboard. If the ASCII keyboard is of the same configuration as the one mentioned in the article, he may use it without making any changes to the truth table or the 1702A memory-circuit programming. If the keyboard is different, a new set of truth tables will need to be made and the 1702A memory circuit will need to be programmed for the ASCII keyboard. A layout of the keyboard should be worked out and a list made of the ASCII6 outputs for each of the keys to be used.

Power must be applied to the ASCII keyboard and the voltages read for bits 1 through 6 for each character. A one will usually be plus 5 volts and a zero will be zero volts or ground potential. (Some characters may have the same ASCII6 data as other characters and this must be allowed for in the keyboard layout.)

The 1702A memory circuit does not need to be programmed according to the ASCII6 data but should follow it as closely as possible. There will be no problem with the letters and numbers characters, but some of the punctuation may not follow a strict ASCII6 conformity. None of the special communications characters such as break, wait, end of message, and end of transmission will follow any kind of ASCII pattern. Three function keys should also be selected for the Store, Send, and Rub Out keyboard functions.

Foreign characters may be selected for the Morse keyboard. The keytops will need to be labeled if the keytops are not available. A larger keyboard may be required for alphabets that require a larger number of characters such as the Japanese Kata Kana radio code. None of the foreign characters will be too long for the Morse keyboard, since the number zero is the longest Morse-code character used. All of the other characters are shorter than the number zero.

If more than 62 characters are needed, it would be best to redesign the Morse keyboard, use ASCII7 data, and use a larger capacity memory circuit. A 2704 EPROM would supply as many as 126 characters and a word space if there were that many Morse-code characters available. Both uppercase and lowercase positions would need to be used on the ASCII keyboard. There would be very few requirements for that type of arrangement.

Most of the integrated circuits are readily available at most of the large electronics parts houses. Prices are still coming down for some of the integrated circuits being used in the Morse keyboard. The prices are down quite a bit since I started designing the Morse keyboard.

In the future, I will be selling some assembled printed circuit boards and possibly some completely assembled Morse keyboards.

Summary

I have enjoyed designing the Morse keyboard and have been using it consistently on the ham bands ever since it was a breadboard circuit. Many hams have mentioned that it was easy to copy code from the Morse keyboard. Many have indicated a desire to try out a Morse keyboard for themselves to see how well they work. Some hams who previously showed very little interest in Morse-code operation have found that it is very enjoyable after all. Morse keyboards are catching on and it looks like there will be very many on the ham bands in the future. ■

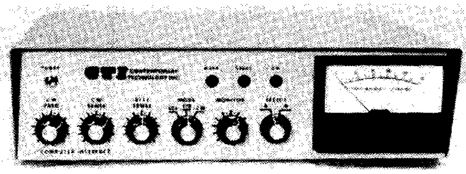
BUILT TO WORK WHEN OTHERS WON'T!



TMC-1B Computer Interface for RTTY/CW

The **best performing unit** under adverse band conditions. **TMC-1B** is designed to compare with the professional equipment that has been on the market for years, not just a piece of gear to get you into computer RTTY. No computer experience needed. Software is included for Vic-20. Will work with most micro computers and with most of the popular software available. Only **CTI** gives you all this and more ★ **Auto start** with a variable control on front panel, will only print on properly tuned RTTY signal ★ L C tuned circuit filters (no active filters) ★ Easy to tune with large meter for greater accuracy, also mark and space LEDs ★ Switchable between 2 rigs (no wires to change) ★ Built-in monitor speaker for monitoring the signal as you send it ★ High gain on input, turn your rig way down ★ Relay isolated CW key and P.T.T. ★ Simple hook-up ★ RS 232 ★ All metal cabinet ★ One year guarantee. **$299.95**

Price includes Vic-20 software in basic on cassette and computer cable

Reveal the Receiver Behind the Specs

Here's a program that will make sense out of all those numbers.

Recently, I found myself coming down with a dread disease. I'm sure you've had it, too. It usually starts with a visit to a friend's shack, a hamfest, or the local radio emporium. You begin to experience an itch that can be relieved only by buying a new piece of ham gear.

As the disease progresses, you pore over glossy spec sheets and read equipment reviews in the ham magazines. It doesn't take long to realize that comparing brand K to brand D is almost impossible when it comes to the receiver specifications.

In one spec sheet, receiver sensitivity is given in microvolts for a 10-dB signal-plus-noise-to-noise ratio. For another rig, the measurements in the lab test give the minimum discernible signal. On occasion you may find a mention of the receiver front-end noise figure. And all of these are tested in different bandwidths. How can you cope?

If that's not enough, today's solid-state transceivers are good enough so that the manufacturers are actually beginning to tell us how their equipment is at handling strong nearby signals. Usually they will spec this as the two-tone dynamic range, but sometimes it is given as the third-order intercept. Is there a way to make a direct comparison?

Fortunately, it isn't too hard to make these comparisons. It's especially easy if you use a computer to do all of the math. Before we get to the program that does this, let's refresh our memories about the specifications that I just mentioned.

Sensitivity

For HF receivers, sensitivity is a measure of the noise generated by the amplifier stages and mixers in the signal path between the antenna and the speaker. It has nothing at all to do with the gain or amplification of the receiver. This is a point of confusion with many hams.

The most common way of specifying sensitivity is with the voltage required to give a signal-to-noise ratio of about 10 dB. The test is easy. Just use a calibrated generator to feed a signal to the receiver and watch an audio voltmeter connected to the audio output. Increase the level of the signal at the input until the voltmeter reads 10 dB higher than it did with no signal. By using the calibration of the output level of the generator, the 10-dB S+N/N sensitivity results.

The reason it is called signal-plus-noise to noise is that you can't turn off the noise when the signal is applied because the noise is made by the receiver itself. Notice that there is no absolute reference to the output level of the receiver. Only the change in the output was measured. Two rigs can have the same sensitivity, but one may produce a very high level of received signal in the speaker while the other may hardly produce an audible output. A spec on overall gain would be nice, but I wish you good luck finding it on the glossy spec sheet!

MDS

The minimum discernible signal that can be heard with a receiver is measured in much the same way as the 10-dB S+N/N sensitivity. The only differences are that the generator level is raised until the audio voltmeter goes up 3 dB, and that usually the MDS is given in dBm (dB referred to one milliwatt in 50 Ohms). By measuring in this way, the signal power and the noise power are exactly the same. To put it another way, the signal-to-noise ratio is 0 dB. Converting MDS to μV for 10-dB S+N/N is mostly an exercise in logarithms.

One trap in the sensitivity specs involves the receiver bandwidth that was used when it was measured. An easy way to make the spec look good is to use a narrower i-f filter. Cutting the bandwidth in half cuts the noise power in half. Then the signal power has to be only half as large as before to give the same S/N ratio. It's not that the manufacturers are sneaky, but they do use different receiver bandwidths in their normal SSB position. To make direct comparisons, you have to take the different bandwidths into account.

Noise Figure

On occasion, the sensitivity of a receiver will be specified as a noise figure. To understand noise figure, imagine that you have a receiver which is entirely noiseless. Connect a 50-Ohm resistor to its input and measure the output of the receiver. Surprise! There is noise there! But you knew that all resistors produce just a tiny bit of noise due to the molecular motion of the resistive material. Your noiseless receiver just amplified that tiny noise.

Program listing.

Now connect my receiver to your 50-Ohm resistor. Set it for the same gain as your noiseless receiver and connect the voltmeter to the output. The difference in dB of the reading on your perfect receiver and that of my real receiver is the noise figure of my receiver.

Since you can't make a perfectly noiseless receiver, you can't measure the NF that way. Instead, a calibrated source of noise is connected to the input of the rig and the output noise is compared to the output with only an input terminating resistor. With suitable calculation, the NF can be found.

One of the interesting things about NF is that the i-f bandwidth has no effect on the spec. This comes about because we are measuring noise-to-noise ratios. Both the receiver internal noise and the noise from the calibrated noise source go through the same filter. This is convenient for the computer program. Internally, it converts all sensitivity specs to NF for ease of calculation.

Dynamic Range

For the contester in a multi-transmitter operation or for the poor soul with another ham just down the street, having a receiver with good dynamic range can mean the difference between enjoying operating or just giving it up altogether.

Solid-state receivers today can be excellent in handling strong signals while listening to weak ones. There are still lots of rigs around, both tube and transistor, that really don't do this well.

The most common way of specifying dynamic range is in terms of the two-tone, third-order intermodulation test. This involves using two signals of the same level separated by about 20 kHz. These signals are fed to the receiver through a combiner and a variable attenuator. The receiver is tuned 20 kHz away from one of the tones. Then the signal level is raised until an audio voltmeter at the receiver output shows a 3-dB change. The difference between the level of one of the tones and the MDS, in dB, is the two-tone dynamic range.

What happens is that the third-order intermod produced by the receiver came up in level enough to be discernible. Because the distortion signal is being compared to the noise, it is also dependent on the i-f bandwidth.

Intercept Point

With the two-tone test, for every dB that the level of the signals is raised, the intermod product goes up 3 dB. By raising the level of the two signals high enough, the intermod product will, in theory, finally rise enough to catch up with the level of the two tones causing the intermod. In fact, this does not happen, but we can extrapolate measurements that were made at lower levels to find out where it would happen. This imaginary point is called the third-order intermodulation-intercept point. It is specified in dBm.

Because we are comparing test signal amplitudes to

the amplitude of the intermod product, the i-f bandwidth is not a factor in the measurement. The computer program uses this for internal calculations because of the bandwidth independence.

The Program

Once the formulas for the conversions are derived, the program is really quite simple. It has five sections. The first part takes care of opening stage business by dimensioning the arrays and setting the constant values.

In the second part, the program asks for the sensitivity spec from the glossy sheet or equipment review. The third section takes in the known dynamic-range specification. Then the computer calculates the equivalent specs for "standard" bandwidths of 500 and 2400 Hz. Lastly, the program tells the computer to print these specs.

To help you modify the program for your own use, the variables used in the program are defined in the beginning of the program listing. So that you will know that your CDC Cyber is finding the right answers, a sample run is included as a check. The program listed was on an Apple II, but the syntax is pretty ordinary and shouldn't present much of a problem in translating to other dialects of Basic.

Trivial

Be wary of anyone who tells you that any particular task for a computer is trivial. Usually those trivial tasks take months to accomplish (as my boss reminds me afterward). It did take me a while to reduce this program to the simple form that you see here. After I was done, even the job done by the program seemed trivial ... until I remembered how long it took to punch in the calculations on my scientific calculator.

I hope this short program makes it easy to compare the competing cures for your itch for new gear. ■

Terrific Top-Band Conversions

Jump up to 160 meters and beat the coming sunspot drought. Surplus gear will get you there cheaply.

Designing ham gear involves many compromises; unfortunately for those of us who operate 160, it seems that many of them end up taking away performance on the top band.

With the new regulations and decreasing sunspots, the number and strength of signals on 160 are going to increase. Will your rig be able to cope? Are you looking for a simple and inexpensive way to add a preselector/preamp to your station? This cheap and easy conversion may be just what you're looking for.

I'm not going to provide a treatise on filter design, so check the references for the data that you need. What this article will do is show you how to adapt any of the HF/MF command-set receivers to provide a foundation for the front-end adjunct that you need.

I chose the command sets for this project for several reasons. The main one is that they are almost a ready-made front end as they are, and the coils lend themselves to easy modification and rewinding. The components are of exceptional quality. In addition, my junk box contains a very high proportion of command-set components.

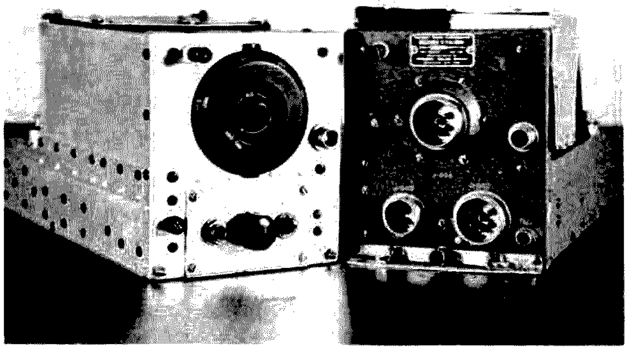

Photo A. The receivers before modification.

If you price the components for the Cohn-type filter from the *Handbook*, you'll find that the current cost of the inductors will be around $50. A used R-11A is $12.95 from Fair Radio (R-22 and R-25 are still available, but about twice as expensive). At our local hamfests they bring from $1 to $10. You can also check with your local OTs; there has to be at least one command receiver left for every ham in the US.

When choosing a unit at a hamfest, the only caution is that those units that have been bandspread (the dial will have homemade markings covering one band) should be bought for coils only as the variable capacitor in these conversions is gutted. Happily, most conversions don't affect the parts used for this conversion. The command sets are probably the most converted piece of surplus gear ever, so your chances of finding one at a hamfest that is completely original are slim.

The command-set receivers cover the range of 190 kHz to 9.1 MHz. Any of them will work for this conversion. See Table 1.

The last command receiver (civilian version) rolled off the assembly lines 20 years ago, the first well over 40 years ago, so even the diehards will have to admit that their usefulness as receivers is about at an end. With this in mind, get out the hacksaw and get ready for the very last command-set conversion.

The simplest passive unit (Fig. 2) uses the variable capacitor and two of the front-end coils (the small cans under the variable capacitor). The others make use of all the front-end coils and

Frequency	Model	Notes
190-550 kHz	R-23, BC-453, R-11	Modify variable
520-1500 kHz	R-24, BC-946, R-22	Scarce, seldom found at hamfests
1.5-3 MHz	R-25, BC-454	Least modification needed for 160
3-6 MHz	R-26, BC-454	
6-9.1 MHz	R-27, BC-455	Padding needed for variable capacitor

Table 1.

the i-f coils; shield cans may be used also.

The front-end coils and i-fs on the early models plug in; those on the later models (no dial) do not. The plug-in feature is nice while testing and constructing, but it is not a necessity. Each of the front-end coils is color-coded for frequency range and function as follows: brown—190/550, orange—1.5/3, yellow—3/6, green—6/9.1, red—.52/1.5. This color code is on the screw holding the coil form to the shield-can base.

The function color code, located in one corner of the shield-can base, is as follows: red—antenna, yellow—rf, blue—mixer.

The i-f cans can be used to house a second filter, as a housing for the amplifier circuit, or as the center inductors for a Cohn-type filter. The 2830-kHz i-fs from the 6/9.1 receiver have a very nice coil form that is easily rewound or modified. The i-f cans can be screw-mounted to the chassis or the tube socket holes can be enlarged and the original plugs used. The mounting brackets will have to be removed to fit the three i-f cans across the chassis as shown in Photo D.

If you do not wish to use the original dial mechanism, or if your unit has no frequency dial, you will have to modify the variable capacitor.

The variable capacitors are rated as follows: 6/9.1, 75 pF; 3/6, 150 pF; the rest are 450 pF. These values are for one section and are approximate as there are some variations in the different models. To lower the capacity, you must remove plates; this is not difficult, but it must be done carefully.

Basic Conversion

First strip the chassis and then the front panel. Set aside the hardware, the front-end coils, the variable capacitor and its shield, the i-f cans, and the small variable capacitor from the front panel. If you have one of the dial-less units, remove the plugs from the front panel. If the aluminum cup is still in your unit, remove it from the front panel also. The front panel should be clean with the exception of the spline shaft holder. If you intend to use the original right-angle setup, leave it on the panel. If not, remove the two pins and then unscrew the nut that holds it to the chassis.

Are you going to use the i-f cans? If so, remove the two tube sockets located immediately behind the variable capacitor shield. Also remove the i-f plugs (if present) by running a screwdriver under the rolled edges and prying up gently.

Now, using a hacksaw with a fine-tooth blade, cut off the rear of the chassis right behind the two i-f holder nuts. This is 5" measured from the front panel. If you will not be using the i-f cans, cut between the shield holder nuts and the first i-f holder nuts. This is 3-3/16" measured from the front panel. Of course, you can leave more rear apron if you need it for relays, power supply, or whatever.

What you now have is a three-section variable capacitor with coils, shield cans, and an enclosure to mount it all in. Now to assemble the finished product.

See Fig. 2. Using the antenna and rf coils, this unit covers the original frequency range of the receiver.

Modify the antenna coil by adding a two-turn coil to the bottom using #20 wire. Connect one end to the ground end of the original coil and the other to an unused pin. Modify the rf coil by removing the pie-wound coil on top of the form and adding a two-turn link as in the antenna coil. Remove the core locks from both coils and screw the cores all the way into the coil form. At this point you may wish

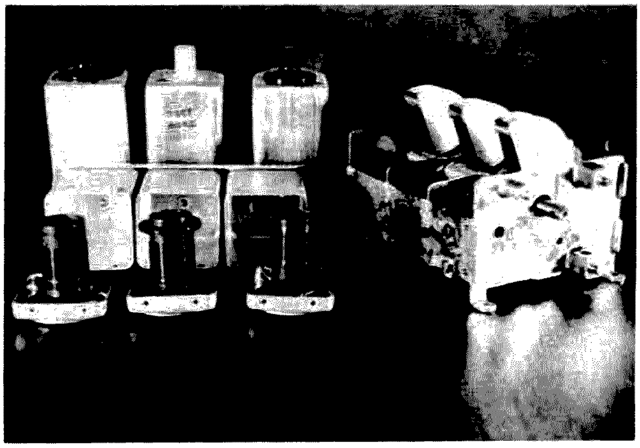

Photo B. The parts used showing a modified variable capacitor.

to remove the shield cans from the bracket and drill holes in them to clear an alignment tool. The shield cans do change the frequency of the tuned circuit. Now, plug or mount the two coils in the first two sockets or holes using the first two sections of the variable capacitor (the ones with the trimmers). Wire the unit to agree with Fig. 2. Make sure that the coupling capacitor does not interfere with the variable capacitor.

Using the trimmers and adjusting the cores, the unit should track across approximately the original range of the receiver. The response is a bit broad on 6/9.1 and adequate on 3/6 and 1.5/3.

See Fig. 3. This adds a preamp and another tuned circuit to Fig. 2. You will have to rewind the mixer coil using the antenna coil as a model. The link is the same and the tap will depend on the gain desired from the amplifier. A dual-gate device could be used here with a gain-control voltage applied to G2. You can use your favorite amplifier circuit here, or even one of the commercial gain blocks. Just remember to use only the amount of gain needed to overcome filter loss or Rx antenna inefficiency—overdoing it will defeat the purpose of the device.

To cover frequencies other than that for which the receiver was designed, you will of course have to rewind (or unwind) the coils and perhaps add some pad-

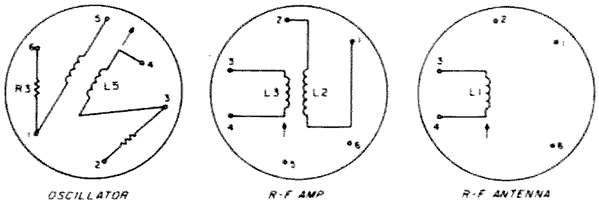

Fig. 1. Typical command-set coils.

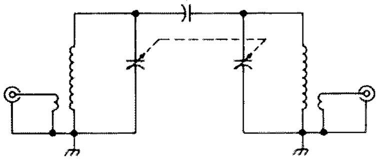

Fig. 2. Simple two-section unit.

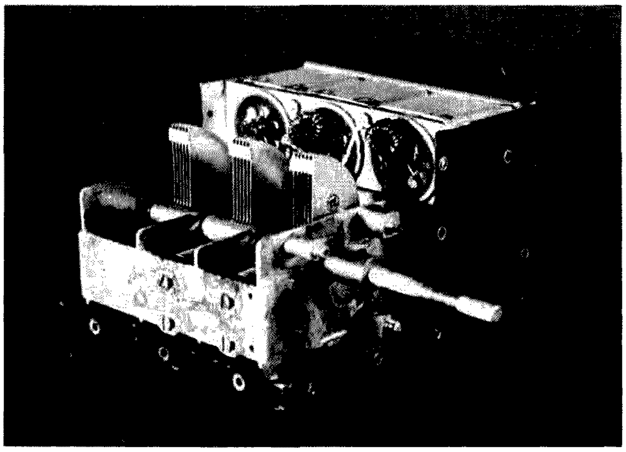

Photo C. Multi-section filter using R-11a parts (no dial assembly), variable capacitor shield removed to show details. Note position of bottom coupling toroid coils.

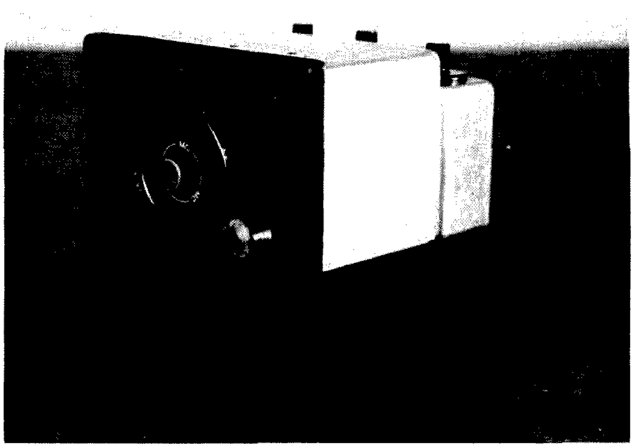

Photo D. Completed unit showing possible placement of i-f cans.

ding to the variable capacitor. If you use the 3/6 and 6/9.1 units, a good starting place for 160 is about an inch of closewound turns of #32 wire. The 190/550 units can be modified by either rewinding the coils or unwinding them. The variables have a bit too much capacitance, but they will work. See Fig. 4. This filter can be made with the coil set from the 190/550 units by unwinding the antenna coil, removing the large coil from the top of the mixer coil, unwinding the small coil, and then unwinding the two coils on the rf coil form until they reach the proper inductance. Unwind only enough from each of the four coils for it to reach the right frequency. This involves a bit of extra "cut and try" time, but it is worth it. Remember that the two center inductors are twice the inductance of the outside coils and that the bottom coupling links and in/out links should be in place as you bring the inductors to frequency.

I have covered only a few of the possibilities for this conversion here; your needs will determine the final form yours takes.

There is room inside the shield can to build the amplifier. The i-f coils can be used to build a second filter for a different range. The switch should have each section shielded to prevent stray coupling. To modify the 450-pf variable capacitors to reduce capacity, do the following:

First, remove the end rotor plate, using long-nose pliers, working it gently back and forth until it breaks free. Remove the next rotor plate the same way. This one and the rest will have to be freed from the band stop bar. Trim the band stop bar after removing each plate. The stator plates are a bit easier to remove. Twist gently at the attachment point opposite the trimmers until it breaks free, then work it up and down until the other side breaks free. Do not put too much pressure on either the shaft or the stator plates or the ball bearings will break free and you will have a Chinese puzzle to assemble. If one or more of the glass beads the stator plates are mounted on is missing, acceptable substitutes can be found at your local crafts shop. Leave six rotor and six stator plates in each section and make sure that the plates are properly aligned. More plates may be removed if the capacity is still too high.

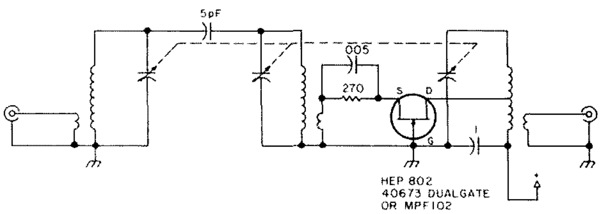

Fig. 3. Preamp and tuned circuit attached.

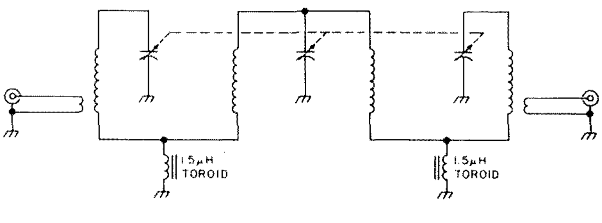

Fig. 4. Multi-coil setup.

More Capacitor Modifications

The antenna section of the variable capacitor either has no trimmer or, if there is one, it has fewer plates than the others. The capacitor that you removed from the front panel can be remounted and used for a trimmer or the trimmer on the shaft end can be used by running an insulated wire from it to the antenna section under the variable capacitor, along the front panel.

To remove the angle drive, first remove the pin in the worm gear shaft, then remove the two gears from the bottom of the capacitor by prying off the retainers with a small screwdriver. Pull the splined end out and then remove the end nut and the worm gear. Remove the gear from the end of the shaft by driving out the pin gently—remember the ball bearings. If the pin is stuck, drill it out. Then remove the triangular plate (this plate helps support the shaft while you remove the pin) and pull the gear off the shaft.

I used as much of the original covers as I could to house the unit. If you remove the drive, you will have to cut a U-shaped slot in the capacitor shield to clear the shaft and coupler.

The time that you spend getting the unit to track will pay off in performance. Take your time and get it right.

I used a GDO to get the circuits close to frequency and then used a signal gen-

erator and scope for final adjustment. If you have access to a sweep generator, it makes alignment very easy.

If you use the unit with a transceiver, automatic switching is a must—the coils don't last long with 100 Watts of rf in them.

If you use the i-f cans to house commercial coil forms, you may have to drill out the center hole for an alignment tool.

For the time spent, this conversion provides a definite improvement in performance at a minimum cost.

A Note to Elmer:

When one of your current crop of KAs brings this article to you and asks if you might have one of these things lying around, don't get misty-eyed and try to explain why you've kept it all these years. He won't understand the sacrilege of applying a hacksaw to a pristine Q-Fiver. I know how you feel, I know how many you converted and passed on to prospective Novices (remember, I was one of them), and yes, I remember the R-24 you put in the '54 Chevy. You saved a hundred bucks and the dynamotor didn't make a bit more noise than a vibrator. I remember, too, when we rewound the coils and put it on 15 and my first VK came back. But, to him it's just a homely box. So bite the bullet and help him out; after all, a ham shack without an ARC-5 (or part of one) isn't really complete! ■

CardSoft: The Transportable QSL Generator

If your machine runs Basic, it can run this program.

Anyone out there priced QSL cards lately? Have you noticed how often you get (or send) an SASE with the ole pasteboard? Well, possibly the day is fast coming when the familiar QSL "penny" postcard will be only a memory (or fading on the wall). I, personally, haven't sent or received QSL cards in several years without an SASE being involved, and at the cost of Uncle's postal service, who can afford it these days? Well, for those who have their own microprocessor (and printer)—and there seem to be rapidly growing numbers of them—here's a solution to part of the problem.

CERTIFICATE

TO ALL WHOM THESE PRESENTS COME: GREETINGS!

KNOW YOU by the Authority invested in Us by the Federal Communications Commission, a regulatory agency of the Government of the United States of America. We do hereby certify that on the date, and at the time and on the frequency herein inscribed:

Two-way radio communication was established between:

WB5LLM

A RADIO STATION licensed by the above referenced Federal Agency, to Us, in accordance with the Rules & Regulations of the Amateur Radio Service.

AND

WD4EDQ

a radio station operating in the aforesaid Service.

P.O. BOX 622
FLORENCE, MS. 39073

WB5LLM's QSL certificate.

The main reason that all this QSL swapping goes on these days, in view of the growth of RTTY, SSTV, FAX, and FSTV, is the need to have the confirming operator's signature on the written confirmation of a completed two-way contact. With this program and your trusty printer, you'll be able to crank out your QSLs neatly, efficiently, and with little cost in either money or time.

Nothing in the book says that a QSL must be on a postcard in two or more colors, costing anywhere from 5 to 10 cents each (or more). So, I sat down one day and faced my Tandy TRS-80C, which I use for RTTY and SSTV, and considered the problem. What I came up with is a program that is usable by almost anyone with the above micro/printer combination that will run in Basic. Some minor changes, such as changing the PRINT#-2 statements to LPRINT, etc., will let this program run on any Tandy micro, Apple, Star, etc., and even on those dedicated micros sold for RTTY use (if they have the Basic capability).

Now to the program itself. First, you'll notice that the DIM statement is in the middle of the program. That's because we're changing the values in the DIM statement every time we run the program and possibly during the program operation. This is when you've run off one or more certificates and then decide that you missed some.

Notice that in line 1 we have cleared 13000 for string-array space. There are fifteen inputs, three of which don't change from certificate to certificate. These are the date statements for the date of the certificate. Since you may be running a bunch at a time, you might as well leave that set at one date (saves typing it in repeatedly). With a space of 13000 cleared, you will be able to enter the data for at least 100 certificates. Of course, this was written on a micro with 32K of memory available (no, I didn't clear out the video area for additional space). If you have a 16K memory, reduce this statement in line 1. That will, of course, reduce the number of certificates you can make in one run.

Lines 200 to 480 cover the actual printing of the text of the certificate and were merely figments of my imagination. The wording was more or less copied from certificates issued by the State of Mississippi but probably is close enough to that used in most certificates to be acceptable. However, if you want to modify it—go to it! Don't forget to follow the REM statements and insert your own call letters and name and address to replace mine.

Lines 550 to 670 are the query and data input area. I don't recommend exceeding 20 characters or more of text in the COMMENTS or ANT. SYS. inputs as this will throw off the balance of the finished certificate. Other than that, have at it.

I've used this for a while now and have had no kickback, and it certainly beats spending an evening writing out QSL cards, one after another after another, etc., ad nauseam. Once you get it debugged (if you make typing errors like I do), just run the program (don't forget to save it, either on tape or disk) and enter the date for the certificates and the number you're running at this time. From then on, follow the prompts.

When you've entered all the callsigns and QSO data for the number of QSLs you're sending out, check your printer. I should mention here that this was written for use with the Tandy Line Printer VII, so if you have a different printer you will want to experiment with the PRINT#-2 (or LPRINT or what have you) statements. You can replace these with control characters that your printer recognizes (you know, CHR$(?)); I didn't bother, as the VII printer seems to like the PRINT#-2 just as well.

Once you have it all in and your printer is ready with the paper lined up at the top, you can follow the instructions and hit ENTER and go on about your business—watch TV, get on the air and let out with a CQ, meet your favorite net, etc. The program and printer will carry on until done and, if you are using the TRS-80C, will sound a tone (if you have the TV volume up, that is) when finished. Alternatively, you can stand or sit there and watch the screen (it displays the data and certificate number of each certificate as it is printing same) and the printer—it doesn't care!

Oh, one last thing—type carefully and don't forget to sign and mail 'em!■

The Six-Meter Vfo That Won't Quit

This hybrid has the best of both worlds. It's as steady as a rock and has broadband tuning.

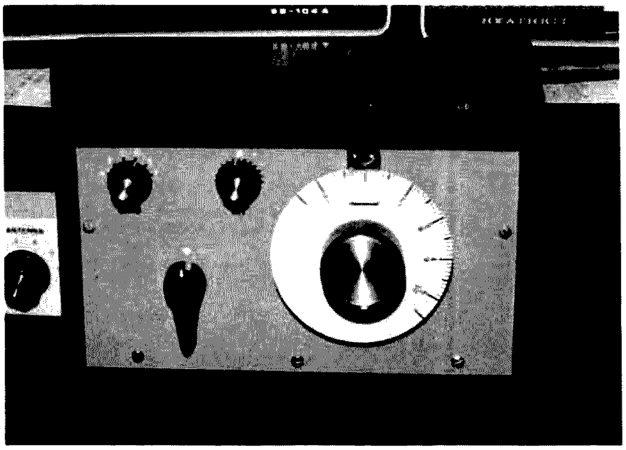
There are certain features I like in a vfo. The prime one is stability as near to a crystal as possible, another is ease of tuning (bandspread), and a third is the ability to tune to any frequency—right down to a Hertz or so. For crystal stability over a narrow range of frequencies, the vxo (variable crystal oscillator) permits infinite resolution. Mixing various crystal frequencies can extend that range, but with considerable complexity and cost. Now that we have ICs that greatly reduce their component count, though, a PLL (phase-locked loop) can provide precise frequencies, at equal spacing over a wide band, quite economically.

The block diagram shows how a PLL with 5-kHz intervals over a range of 500 kHz is combined with a vxo that has analog tuning over a 5-kHz range to give an output of 5.5 to 5.0 MHz. In this configuration, the 5.5 represents the low transmitter frequency and the 5.0 represents the high transmitter frequency. It was chosen because that's what is required by the Heath SB-104 with which it was to be used. By careful selection of the vxo and PL frequencies, the output can be any 500-kHz segment desired, and by choosing the vxo frequency to sum with the PLL generator, the output will not be inverted.

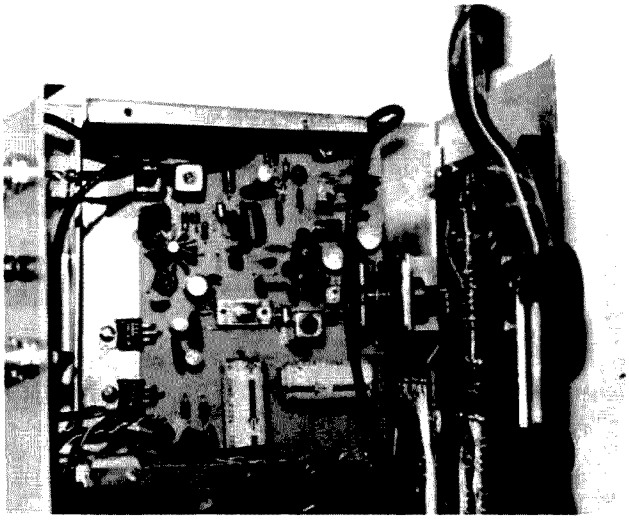
With a 5-kHz reference for the PLL, the "warping" of the vxo at 7.42 MHz is easily attained and quite linear. It also lets us use most any of the PLL chips found in the later CBs as well as the 10.24-MHz crystal associated with it.

The circuit is relatively simple. Q1 is the 10.24-MHz reference oscillator. Q2 amplifies and shapes its output to drive the 7473 divide-by-two counter. Further division takes place in the PLL (MC145109) to get the 5-kHz reference. Q10 is the vxo; its output goes to the mixer (Q11). The vco is Q8, and its frequency is controlled by the output of the phase detector in the PLL chip. The output of Q8 is the other mixer input and also goes to the LM703 buffer/amplifier. It, in turn, drives Q9, the vfo output stage. The mixer output is filtered and amplified by Q12 and then applied to the signal input of the PLL.

Q4 adds or removes a 4.7-uF tantalum capacitor in the timing network of the 555. The 555 runs all of the time, but its output is diode-gated by the UP or DOWN switches, which also determine which way the 4029



Vfo in operating position, showing panel layout.

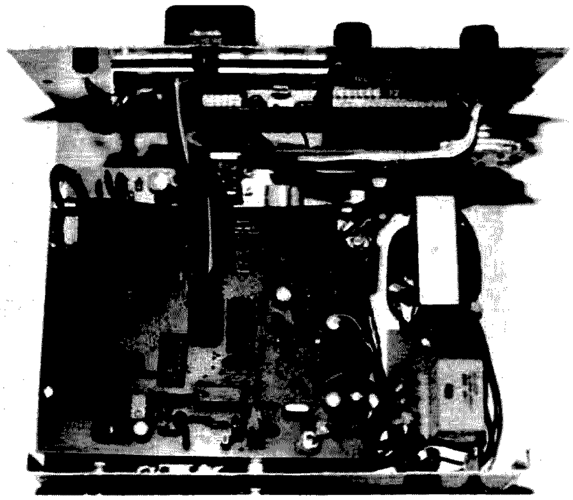


Inside view of oscillator circuit board shows vxo frequency trimmers, tuning capacitor, and voltage regulators.

counters count. Q3 shapes the gated output to ensure clean counting. The first counter is for the 5-kHz increment, and the other counter outputs step the remaining digits. SO1 is for the display connections. If the display is omitted, SO1 can be eliminated or jumpered (pin 2 to 14, 3 to 13, 4 to 12, 5 to 11, 6 to 10, and 7 to 9; pins 1 and 8 are left connected to the other circuitry).

The LD LED is enabled by Q5 when the PLL is in lock. When the PLL is not in lock, Q6 disables the vfo output by applying excessive bias to the LM703 through diode DA. Q7 enables the out-of-band indicator LED and disables the vfo output in the same way as Q6. Out-of-band in this circuit is anything outside of 5.0 to 5.5 MHz and may need modification (or elimination) if, because of the accuracy of the other transceiver crystals, the vfo must be shifted up or down.

The display portion is not needed with the SB-104 or similar transceivers with self-contained counters. For use with other rigs, it's a nice feature. When the display is used, PI-1 replaces the jumper in SO1, and the 4029 counters are set in the BCD mode by inserting a jumper from pin 9 to ground on the two most significant digit 4029s. The counters directly drive 4511 BCD-to-7-segment encoders and also two 4008 full adders to convert the BCD to binary for the PLL. Another 4008 allows adding 5 to the third digit (hundred thousand Hz) of the display. This permits setting the bandswitch of the vfo to 3.5 and 28.5 and counting from there on those band segments. The two most significant digits of the display are not a part of the counter but are set by a diode matrix and the bandswitch.



Upper portion is the display board and the PLL section is in the lower left. Power transformer is on the right.

The RIT circuit uses a varactor and a 10k pot to vary the frequency of the vfo in the receive mode. In the transmit mode, a positive regulated voltage is applied to the varactor to reduce its effect to a minimum. This is accomplished by Q13 and Q14 by the ap-

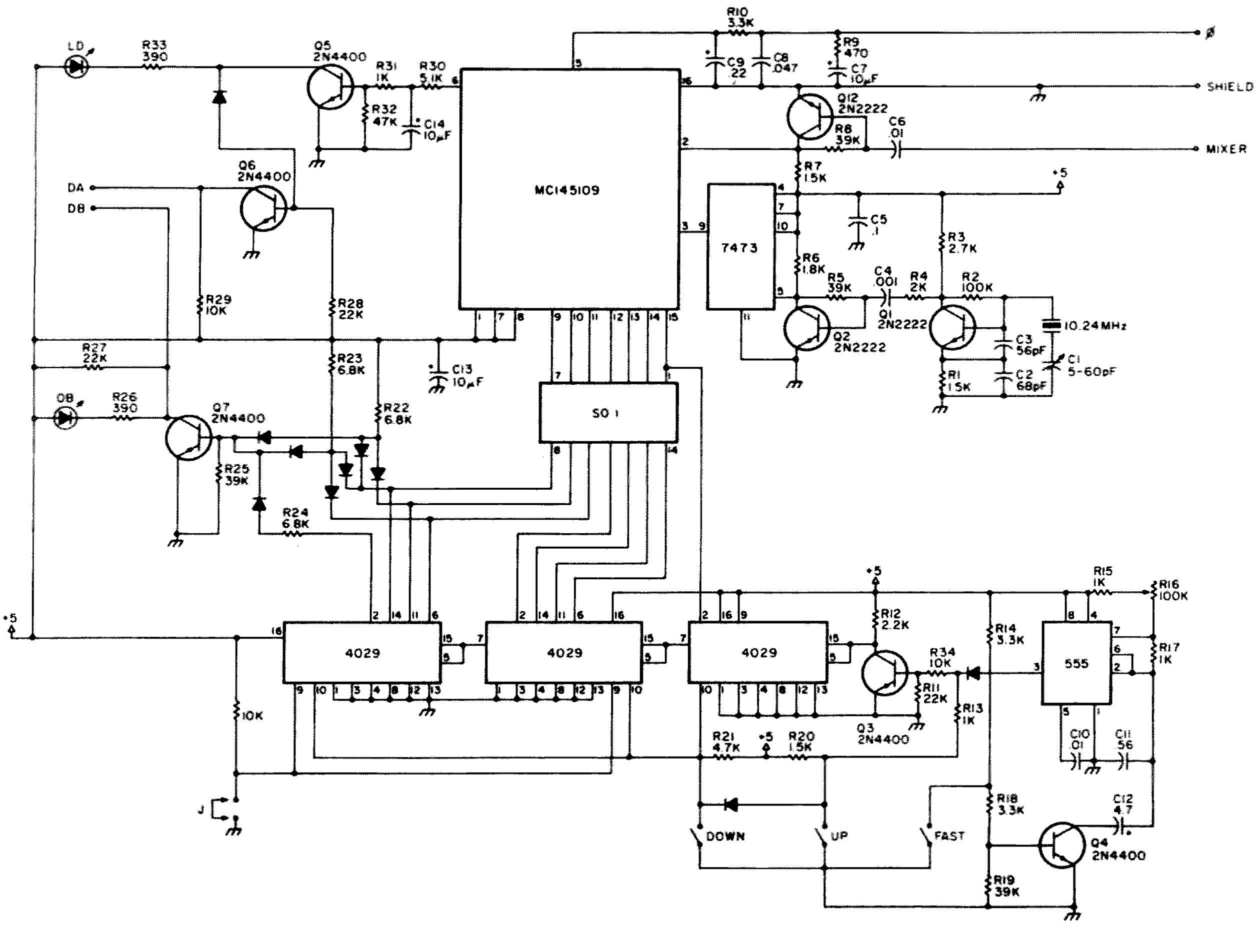


Fig. 1(a). PLL.

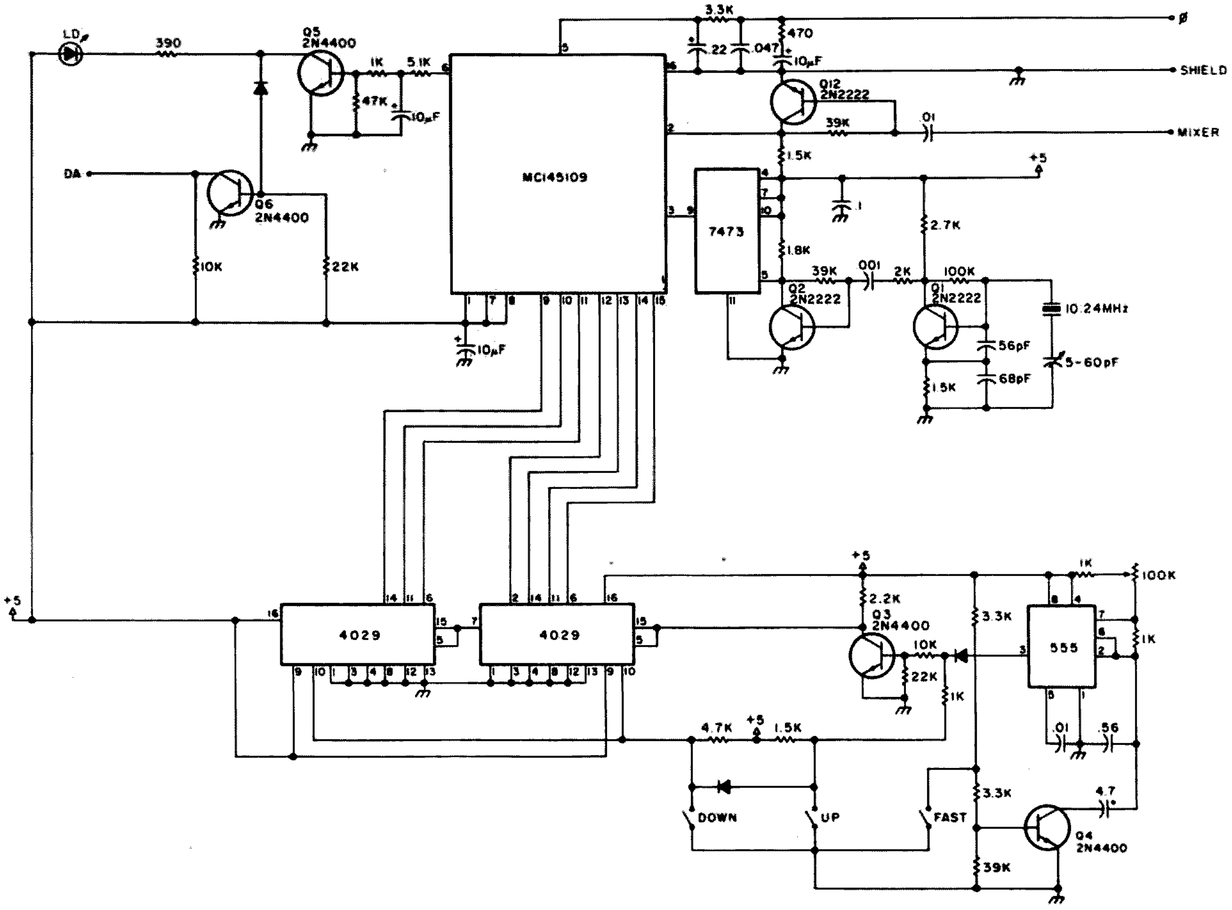

Fig. 1(b). Simpler layout for PLL.

plication of a positive voltage to the T/R terminal. In the same action, C_A is diode-switched into the circuit to cause the vxo to operate at the mid-frequency of the receive RIT range. Because the varactor is, in effect, in series with the tuning control (C_T), the RIT range varies from ±200 Hz at the minimum setting of C_T to ±360 Hz at its maximum setting.

Any regulated power supply providing +12 and +5 volts is satisfactory. The simple one shown in Fig. 4 was used in the prototype. Current requirements, including display, are about 300 mA total.

Although I used three circuit boards because that worked out best with the case I wanted, there is no good reason why it cannot be built on one or two boards. Layout is not particularly critical except for the usual considerations given to rf and digital construction, such as short rf leads and good decoupling. The bypass capacitors for the oscillators and integrated circuits should be placed as close as possible to the relative component. Except for L_A and L_B, all of the inductors are high-Q ferrite chokes. L_A and L_B are miniature rf transformers removed from a CB board and rewound. Because of the variations in permeability and winding area, the turns and wire sizes are not given. Both L_A and L_B should have unloaded Qs above 50 and be adjustable. T1 consists of a 60-turn primary and a 30-turn secondary of #30 enamelled wire, on a T-37-2 core. In the frequency-controlling portions of the oscillators, NPO capacitors are recommended. The other small capacitors can be mylar™, ceramic, or mica; the polarized ones, either tantalum or electrolytic. The nominal frequency of the crystal in the vxo (Q10) is not critical. Crystals from 7.422 to 7.425 were easily tuned.

Although many of the parts used can be salvaged from a CB board, two low-cost transistors were used throughout. In most cases, any of the NPN rf low-power transistors in a CB will probably work in place of the 2N2222, and audio and switching NPNs can replace the 2N4400. C_T is the fine-tuning control that covers only 5 kHz, so it doesn't need much knob reduction. I used a 5:1 vernier and I wouldn't recommend any larger ratio.

The first step in tune-up is preliminary adjustment of the vco. With power applied, temporarily ground the phase-detector output by shorting the .022 capacitor in the Ø line, set C_E to minimum capacity, and determine if Q8 is oscillating. This can be done with a counter or by placing a lead from a shortwave-receiver input near C_D and tuning the receiver in the area of 4.5 to 6 MHz. If it is not oscillating, increment C_E to larger capacities and continue to check until its signal is picked up. Then adjust L_A so the generated signal is about 5.55 MHz. Remove the short across the Ø line.

The initial adjustment of the vxo (Q10) is done in the receive mode with no voltage applied to the T/R terminal and with the RIT pot at its middle position. Loosely couple a frequency counter or receiver input to the source of Q10, set C_A to its middle position, and set C_B and C_C to their minimum capacities. Check the frequen-

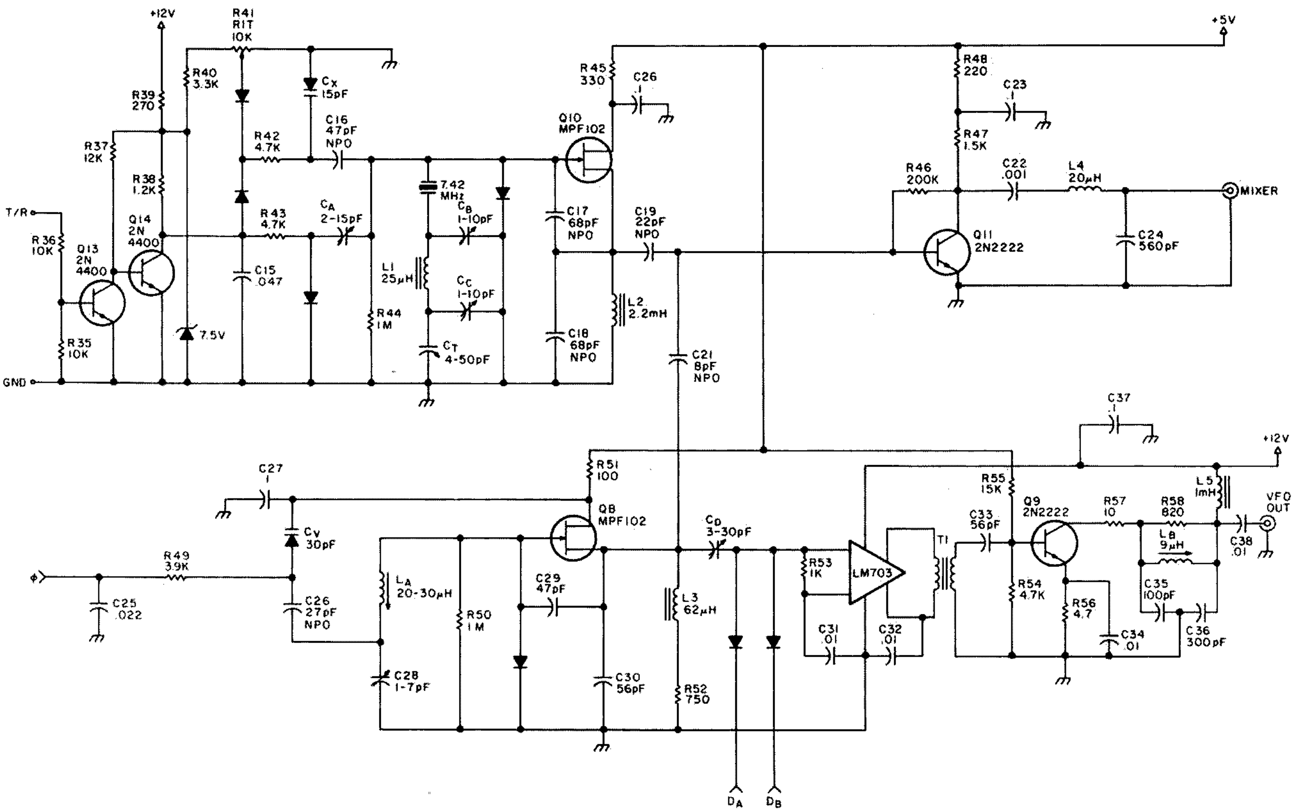

Fig. 2. Oscillators.

cy of Q10 at maximum and minimum settings of C_T. At 10 degrees short of minimum capacity, the desired frequency is 7.420 MHz. At 10 degrees short of maximum capacity, it should be 7.415 MHz. The ten degrees on either end allows for some overlap and keeps the dial markings in the more linear range of the capacitor. As C_B and C_C interact with each other, it is necessary to repeat their adjustments using C_C when C_T is near minimum and C_B when C_T is almost fully meshed.

When these adjustments are completed, set C_T near maximum and note the frequency. With +12 volts applied to the T/R terminal, adjust C_A to the same frequency. Leave the 12 volts connected to the T/R terminal until the rest of the alignment is done. If there are circuit errors, much time can be saved if the rest of the checks and adjustments are done systematically.

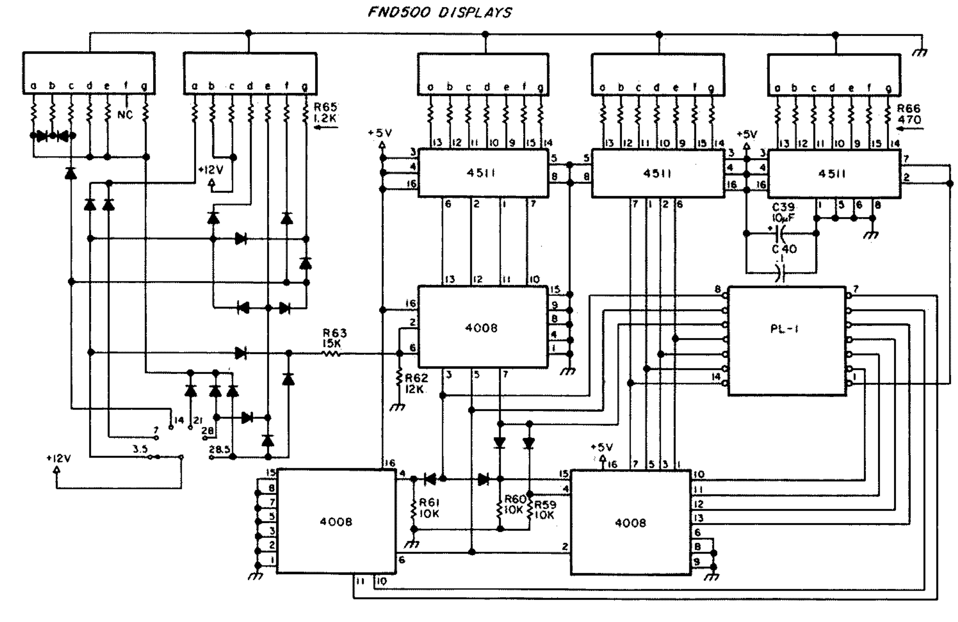

Fig. 3. Display.

Check the waveform at pin 9 of the 7473 with a scope. It should be a clean 5.12-MHz square wave. In lieu of a scope, loosely couple a receiver input to pin 9 by laying the antenna lead close to it and tune the receiver to 5.12 MHz. If the signal is steady and pure, the reference oscillator can be assumed to be working OK.

To check out the counter, measure the dc voltage present at pin 15 of the PLL (MC145109). It should swing from zero to nearly +5 volts as the counters are enabled by either the UP or DOWN switches. Check each of the counter output lines, pins 14 through 9 on the PLL. They, too, should alternate between zero and +5 volts, but at successive-

ly slower rates, when the UP or DOWN switches are closed. When you're satisfied with the results, run the counter up or down until pins 9 through 15 are all at zero volts. This represents a setting of 384 for the divide by N counter in the PLL. As the reference frequency is 5 kHz, the phase detector will lock on a frequency of 1.92 MHz (384 × 5000). If the vxo tuning capacitor (C_T) is set near minimum to a frequency of 7.420 MHz, then the phase detector in the PLL will try to tune the vco to 5.5 MHz (7.42 − 1.92). Note that the varicap in the vco returns to a positive voltage so the vco frequency will be lowered as the 0 voltage becomes more positive. Adjust L_A until it locks with a voltage of about +.3 volts at pin 5 of the PLL. Run the count from the 4029s to 483 (2.415 MHz) to make sure it stays in lock, then stabilize the slug of L_A with hot wax.

To adjust the vfo buffer and output, temporarily connect a 47- or 51-Ohm, 2-Watt carbon resistor across the vfo output jack and tune L_B for maximum output at 5.2 MHz. Adjust the rf output to about one volt with C_D, and remove the 2-Watt resistor.

The 10.24-MHz reference oscillator is most easily trimmed with the aid of a frequency counter. If the vfo is to be used with a transceiver with a built-in counter, precise alignment is not that important. In any case, you may want to calibrate the 5-kHz dial of C_T.

For the UP, DOWN, and

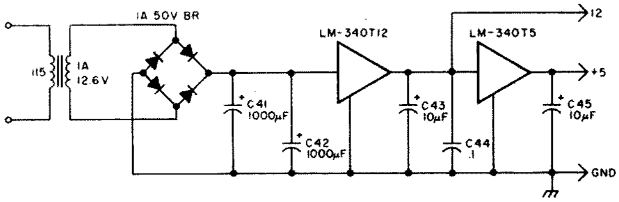

Fig. 4. Power supply.

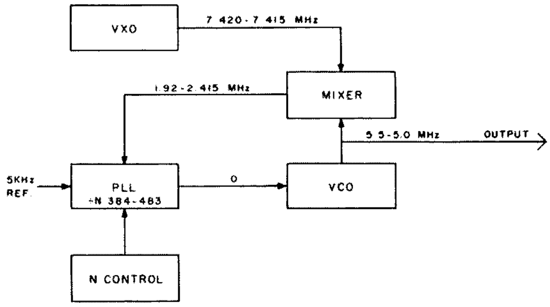

Fig. 5. Block diagram.

FAST switches, I used calculator keypads and the shaft and bushing of a discarded pot. A clockwise pressure closes the UP switch, counterclockwise the DOWN, and a gentle push puts it in FAST.

Construction and adjustment were not difficult. And best of all, several months of use have demonstrated its stability, reliability, and operating ease. It gives me what I want: A rock-hard signal with a soft touch. ■

COMPLETE READY-TO-USE SYSTEMS

ATV TRANSMITTER/CONVERTER

$399

TC-1

★ High resolution and color video
★ 10 watts output
★ Broadcast standard sound
★ Tunable downconverter and preamp

Connect to the antenna terminals of any TV set, add a good 450 MHz antenna, a camera and there you are . . . Show the shack, home movies, computer games, video tapes, etc.

ATV DOWNCONVERTER

For those who want to see the ATV action before they commit to a complete station, the TVC-4 is for you. Great for public service setups, demos, and getting a buddy interested. Just add an antenna and a TV set tuned to CH. 2, 3, or 4 and plug in to 117 volts a.c. $89.00

TVC-4

TVC-4L extra low-noise version . . . $105 delivered in USA

MODULES

TXA5-4 Exciter/Modulator . . . . . . $89.00 ppd. Wired and tested module designed to drive PA5 10 watt linear amplifier. The 100 MHz crystal design keeps harmonics out of two meters for talk back. Video modulator is a full 8 MHz for computer graphics and color. Requires 13.8 VDC reg. @ 70 ma. 80 mw output power. Tuned with crystal on 439.25, 434 or 426.25 MHz
Dual frequency model available . . . . $115.00 ppd.

TVC-2 ATV Downconverter . . . . . . $49.00 ppd. Stripline MRF 901 preamp and double balanced mixer digs out the weak ones and resists intermod and overload. Connects between UHF antenna and TV set. Output channels 2 or 3. Varicap tuner 420 to 450 MHz. Requires 12 to 18 VDC @ 20 ma.
Extrasensitive TVC 2L with NE64535 preamp (.9 dB NF) . . . . $59.00 ppd.
Supersensitive TVC 2G with GaAs Fet preamp (.5 dB NF) ant. mount . . . . $79.00 ppd.

FMA5 Audio Subcarrier Generator . $29.00 ppd. Puts audio on your camera video just as broadcast does at 4.5 MHz. Puts out 1 V p-p to drive TXA5. Requires low Z mike, 150 to 600 Ω and 12 to 18 VDC @ 25 ma. Works with any transmitter with 5 MHz video bandwidth.

PA5 10 Watt ATV Power Amplifier . $89.00 ppd. The PA5 will put out 10 watts RMS power on sync tips when driven with 80 mw by the TXA5 exciter. 50 ohms in and out plus bandwidth for the whole band with good linearity for color and sound. Requires 13.8 VDC reg. @ 3 amps.

Let P.C. put you on the air and SAVE!
All four modules —
Complete System price $245.00
SAVE $11.00 over price if purchased individually

Call or write for our complete catalog of specifications, station setup diagrams, and optional accessories which include: antennas, modulators, test generators, cameras and much, much more. See Ch. 14 1983 ARRL Handbook.

Foolproof Logging

KL7GRF designed a logbook program that any TRS-80 owner can use. And it manages your QSLs, too.

As all amateurs know, the rules for logbookkeeping have been relaxed considerably by the FCC in recent years. For most amateurs, however, the log is akin to a ship's log. It is kept and kept accurately.

In these days when home computers are invading households all over America, the ham shack is one of most likely places to find a home computer. One of the most common of these is the Radio Shack TRS-80*, the largest-selling home computer in the world. Software is plentiful for the TRS-80, and programs of almost any kind can be found at your local computer store, which brings me to the subject of this article.

The home computer is a natural for keeping a log and keeping it well. Described herein is a logkeeping program that should satisfy the requirements of almost any amateur. In designing this

*TRS-80 is a trademark of Radio Shack, a division of Tandy Corporation.

Program listing.

program, I attempted to make it versatile and easy to change to fit an individual amateur's requirements. Most of all, I attempted to make it compatible with 16K cassette TRS-80 owners, as well as those with disk-drive systems. It's a toss-up as to which peripheral most will upgrade to from the cassette-based system, a printer or disk drives. Another consideration was keeping it suitable for those who use cassettes with a printer, but don't have disk drives.

The program uses sequential I/O techniques instead of random-access files. I chose this method so that the program could be easily modified to run on cassette as well as disk. Some purists will argue that random I/O is the only way to go. However, the average amateur does not make more than 10-15 contacts a day. Therefore, the in-memory storage of information is practical if the log and its data are based on daily files instead of keeping a month's log in one file on a disk.

This program is written in Microsoft Basic for the TRS-80, but should be easily adaptable to other computers, such as Apple, North Star, and others.

The program features the following:

1. In-memory log for all contacts in a day's operation.
2. Add-on to a log or previously-filed log.
3. QSL information and management of received QSL as well as outgoing QSL information. Manipulation of QSL files is provided.
4. A hard-copy printout of each day's log data.
5. Permanent filing of log data on disk or cassette on a daily basis.
6. Compatibility with 16K as well as larger systems.
7. Day's log summary is provided on the video terminal.
8. Allows for 100 entries a day (as is), which should be changed for smaller systems and increased for larger systems if desired (details on this later).
9. "Customizing" the log to fit your requirements is easy.

```
           LOG BOOK FOR AMATEUR RADIO STATION KL7GRF

....................................................

1. CREATE A NEW DAYS LOG.
2. ADD TO EXISTING LOG.
3. UPDATE QSL INFORMATION
4. SAVE LOG TO DISK.
5. LOAD LOG FROM DISK.
6. SUMMARY OF DAYS LOG.
7. OUTPUT LOG TO PRINTER.

Fig. 2. Sample of QSL update on video display.

The Program

The program is numbered starting at line 10 in increments of 10, so just set the TRS-80 to AUTO 10,10 and start entering the program. Lines 10-80 set up the variables, DIM statement for the actual data entries (L$), and establish data statements for use later in the program. Change string variable C$ in line 50 to your own callsign. String variable T$ in line 50 is set to UTC (Universal Coordinated Time); if you desire to set time inputs to local time, change T$ to "PDT" or whatever. Do not exceed three letters in T$ or it will throw off the PRINT@ strings in lines 60, 70, and 80. The CLEAR statement in line 10 should be changed for smaller systems as well as the DIM stratement in line 20 (more on this later). Variables SK and SW are switches used to reset all variables to null for restarting a new log or loading data from disk or cassette.

Lines 110-160 are merely there to prompt you through the first few times you use the program; they can be deleted when you are familiar with the program, shortening execution time and saving memory. The remainder of the program should be unchanged except as described later when detailing changes for the cassette-based system. Disk-drive operators can use the program "as is."

                END OF LOG FOR MAY 21, 1981
```

Fig. 3. Sample of printer output.

Operation of the Program

Extensive use is made of the INKEY$ function in the program, making it faster in use. The only time the ENTER key is used is when more than one character is to be entered. When you see a letter in parentheses, "(C)", it means that a single key input is requested and the ENTER key is not required. When the ENTER key is required, it will appear as "(ENTER)" a value. Lots of error trapping is included, so it is hard to make a mistake. Wherever a mistake is possible or imminent, a message is provided on the screen and the opportunity to exit the danger area is provided by an exit function.

No delete-entry routine is provided, since a log is defined by law as a legal document. Corrections should be made by drawing a line through the deleted or changed entry. They should then be initialed by the person making the change(s). Any changes to the log can be inserted on the hard copy produced by the printer. The printer output routine is based on an 80-column printer. The format of the output to the printer is shown in Fig. 3.

The DIRECTORY video display (Fig. 1) is single-key entry. Selecting "1. CREATE A NEW DAYS LOG" clears and resets all variables. If data is present in memory, you will be warned and given the opportunity to exit to the directory and save the data to disk. If the data has already been saved and you want to start a new log, merely press the (C) key and the program will proceed to start the new setup. If no log data is present in memory, the program will proceed normally. A word of warning: When starting a new log, you will be asked for the date in a specific input manner, i.e., MAY2181. Note that no spaces are allowed. The date display is derived from this input and, more importantly, the Filespec for writing to disk is derived from it. The program checks to make sure you did in fact put 7 characters in and gives you an error message if it detects any fewer or more than 7 characters. No checking is done for proper sequence. A disk and cassette file will not accept a number as the first character of a filespec, so pay particular attention to this question.

"2. ADD TO EXISTING LOG." If data for a given day is already in memory and you wish to add to it, just press 2 and it will select the next available sequential number available and display the data input form. If you wish to add on to a filed log (on disk or cassette), load that log through the "LOAD LOG FROM DISK" function and then select the "ADD" function. Don't forget to save the log back to disk. Killing the old file is not needed since sequential techniques write over the old file which will have the same Filespec as what you write back out after additions to the log. This is a bit of a problem for cassette systems, as will be described later.

"3. UPDATE QSL INFORMATION" is a routine to account for outstanding QSL cards received. The procedure for this is to load the file for the data to be updated through the "LOAD FROM DISK" function. Then use the "SUMMARY" function to locate the entry you wish to update (or use the printed copy previously printed to locate the entry number). Enter the "UPDATE" function and make the corrections. The display for "UPDATE" is shown in Fig. 2.

"4. SAVE LOG TO DISK." When completing a day's operation, use this function to save the data to disk. The Filespec is automatically created using the date question described earlier. Use this function to save back to disk after using the "UPDATE" function or "ADD TO LOG" function if a file was loaded for addition of entries.

"5. LOAD LOG FROM DISK" is used to retrieve old files for QSL manipulation or "ADD." You will be asked the date question again here. Use care: The computer creates the Filespec from this information.

"6. SUMMARY OF DAYS LOG" gives a rundown of the day's operation (see Fig. 5). This can be looked at after loading an old file or with data already in memory.

"7. OUTPUT LOG TO PRINTER" provides neat, orderly output to a line printer for permanent record purposes. It is based in format on many of the commonly available logbooks (see Fig. 3). Full pagination is

1. Change line 10 to: CLEAR4000
2. Change DIML$ statement in line 20 to: L$(50,10)
3. Change "DISK" to "CASSETTE" in lines 180 (2 times), 950, 960, and 1140

provided for 8.5 by 11 inch paper including page numbering.

Data Input to Log

Data input format to the log is shown in Fig. 4. When this display is presented, a series of graphic blocks will be displayed to indicate the maximum length of the input. You must put an entry into each data block. Merely pressing ENTER will cause an error message and a return to that data entry. On the other hand, exceeding the blocks will also cause an error and a reprint of the requested data. The only entries that will accept no data input are REMARKS, QSL SENT, and QSL RCVD. Since this is optional information, the leeway is allowed. After completing the "form," you will be asked if the data is correct; if not, the program returns to the same entry number and resets the block in order for you to retype the entry. If it is correct, the program will ask if you want to add another entry. If not, you return to the directory. The time entry is done in military 4-digit style, i.e., 2343, 0416, etc. No commas or quotes are allowed by the TRS-80 and any data entered after a comma is inserted will be cut off. Periods are OK. The requirement for power input in the log was not forgotten. The TRS-80 video display is limited to 64 characters and addition of power input would have crowded the display quite a bit. So, I chose to leave the power input for the remarks data input.

QSL Update

This operates in a manner similar to that of DATA ENTRY, except that you only manipulate the QSL information.

Hints

Save your data off to disk often during a day of operation to prevent loss of data from accidental turning off of the computer, power failures, etc. Use particular care in entering the PRINT@ variables in lines 60, 70, and 80, and make sure you see and enter the % sign on the extreme right of variable G$. For disk systems, set the clock in the expansion interface from DOS prior to going to Basic; the time will then appear right next to your callsign through most of the program. Single-disk-drive owners can use this program by killing off all of the programs on a TRS-DOS diskette and loading this program and maintaining all data files on the same disk. Multiple-drive owners should maintain separate data diskettes. If you own a printer, then hard-copy files only could be kept, eliminating the need for data diskettes or cassettes. To increase the handling capabilities for larger systems, change the CLEAR statement to a larger value, such as 10-12000, and change all 1 to 100 FOR NEXT loops to a value of 300 or so. Contest logs are possible by fixing certain variables to fixed values and inserting a duplicate-checking routine. Write if you want information on this; the changes are beyond the scope of this article.

Those having heavy fingers on the keyboard should beware: If you are not used to single key entry, it's fast. Be sure to experiment with small amounts of data until you get the feel of the program, rather than commit large amounts of data.

Cassette Operation and Changes

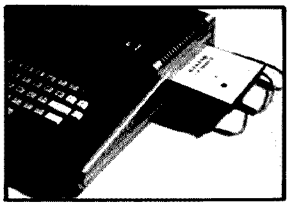
Ah, yes, the cassettes, the one true headache of home-computer operation. This program will work very well with cassette-based I/O, but it will be very slow on the I/O operations (probably slower than you could ever believe). You must have a minimum of 16K memory for this program. I have intentionally reduced the CLEAR, DIM, and FOR NEXT loops, since you will have trouble finding a digital tape long enough to hold 100 entries. The changes to the program required for cassette operation are shown in Table 1.

Summary

Contained in this article is a program that is versatile, fast, and easily changed to fit individual requirements. I hope you have fun with it. Write me with any questions.

If demand is high enough, I would consider producing this program on formatted disk and/or cassette. Contact me for information on this. ■

MORSE CODE from MITRONIX



Turn your Radio Shack Color Computer into a complete Morse Code terminal.

MITRONIX MODEM—Interfaces the computer to your transceiver via the ROM PAC slot.

Cartridge: $54.95

—You have your choice of 5 CW programs to pick from including:

—MITRONIX TRANSLATOR
This Machine Language program allows you to transmit & receive from 5-60 WPM. Features split-screen with reverse video receive, a 1024 character TX buffer, auto CQ, & 4 message memories.

Cassette: $26.95

KA9FSQ PERSONAL CW MAILBOX—
Written in COLOR BASIC, this program allows you to transmit to 50 WPM, & receive to 30 WPM. In the MAILBOX mode, it will answer a CW call, get other station's call letters, message, data & time, and store it in memory for instant recall when you return. Also hard copy.

Cassette: $21.95

For additional information and programming, write to:

The Program No Net Control Should Be Without

Every net generates lists. Keep yours up to date with this TRS-80 Basic program.

Soon after we began the Central North Carolina Weather Net on the two-meter band, the net-control station needed a better way of keeping track of the hams who had joined the net. In order to facilitate call-up, the net-control stations decided to maintain a sequential list of members, each with an assigned number. At the same time, we needed to determine quickly whether a station checking in had been assigned a number—that is, whether he was already listed as a member of the net. After inadvertently assigning several stations multiple numbers, I wrote a net roster program to keep track of the net membership.

The program lists stations in numeric sequence, thirty at a time, for net call-up and searches for a given call to determine if it is in the register; it corrects an erroneous entry and adds a new member's call to the register.

This program is organized as a series of subroutines called by a main calling program. This approach simplifies programming and debugging; if I want to change one of the features in the program, I change only one subroutine.

Overview

The program stores each member's call letters, county of residence, and name. The program includes the following routines: read data from tape, save data to tape, list a block of 30 net members, search for and display a specified call, sort the data by call letters, change an entry, and add an entry. The Search routine is fast—about ½ second to search up to 511 entries for a specified call.

Fig. 1 shows a flowchart of the program. The program first initializes variables (lines 10–20), reads a look-up table of county names (subroutine at line 590), and reads the file of net members from tape (subroutine at line 80). You can bypass this tape-read routine if you plan to make all the entries from the keyboard. Immediately after reading the tape, the program sorts the data by call letters. The Sort routine does not move the main files around physically, but sets up a list of integer pointers indicating the alphabetic order of the callsigns. The callsigns and related data remain in their original order. You can reenter this routine later to include any new entries in the sorted array of pointers.

At this point the program prints the menu of commands (line 50): #—LIST, 'C'—CHANGE, 'SAVE', 'A'—ADD, 'S'—SORT. The # represents a numeric input. Any entry other than those on the menu initiates a search for that entry among the list of call letters.

When you enter a number, the computer lists the net member with that number, plus the next 29 members (subroutine at line 410). For example, if you enter 25, the program lists the call, county of residence, and name of the operator of the twenty-fifth through the fifty-fourth members of the net. This facilitates calling up the net. At the start of the net session, you, as net-control station, announce, "Net members, numbers one through thirty check in now." With the first thirty members on the screen, you can greet each member by name even if your memory for names is terrible.

When a member checks in who does not remember his number, enter his call letters. The computer checks to see whether the entry is a C, S, SAVE, or A. If it is none of these, the computer presumes the entry to be call letters, calls the subroutine at line 460, and initiates a binary search through the net roster for that call. Even though it is programmed in BASIC, you can search more than 500 entries in less than ½ second. If a match is found, the call letters, county of residence, and the operator's name are displayed at the center of the screen. If a match is not found, you can add the new station to the roster.

To add a new member to the roster, enter A. The subroutine at line 530 re-

quests call letters, county name, and operator's name. The program stores the call letters and operator's name in memory, but does not store the entire county name. The program stores an integer number that identifies the appropriate county from the list of counties which you read in at program start. This allows many more entries in my 16K machine than would otherwise be possible.

To change an entry, enter C (subroutine at line 330). You can reenter a call, county name, or an operator's name to correct an error. If you do not wish to change the entry, press Enter to retain the original content.

The binary Search routine finds only those calls which have been ordered by the Sort routine. Any time you enter one or more new calls or change one or more call letters, you need the Sort routine. This routine begins at line 120.

In order to save an updated roster to tape, Enter SAVE. At this point, the program gives you an option to turn on the recorder in order to cue the tape or to continue with the Save routine (subroutine at line 270). Outputting 4 to port 255 cues the tape. This turns on the tape recorder motor in Model I machines. Then the program enters a timing loop for a few seconds before turning the recorder off. This same routine spaces into the tape a few seconds before saving the data when you continue with the Save routine. The cueing routine may not work on Model III TRS-80s. As presently constructed, the program causes the computer to first CSAVE the program, then save the data to tape.

Sort and Search Routines

A children's guessing game goes like this:

"I'm thinking of a number between one and fifty. Guess what it is."

"Is it 10?"

"No, you're too low."

"Is it 40?"

"No, now you're too high."

And so on. The first time you played this game, you probably guessed numbers randomly until you guessed the correct number. In the example above, that could mean as many as fifty guesses. After a few such games, you may have discovered that you could guess the correct number much faster if you first guessed the middle number of the range of possible numbers—25 or 26 in the example above. If that guess is too low, the correct answer must be between 26 and 50. You then guess the middle of that range—38. If that is too high, you next guess the midpoint of the range from 26 to 37, and so on. Each time you divide the size of the range of possible answers by *two*—hence the name *binary* search. Using the binary search, the correct number between one and fifty will always be found by the sixth guess, at the worst. That is a lot faster than 50 guesses! More than 500 entries can be searched by this method with no more than nine guesses.

In the net roster program, membership is sorted by call letters. A pointer table indicates the order; the master list is not reordered. Moving integers in memory is faster than moving strings. The master list remains in numerical order, which is convenient for display during net call-up.

The first entry in the pointer table is the subscript of the call which would be first in alphabetical order. The second entry in the pointer table is the subscript of the call which is second in alphabetical order, and so on. For example, suppose there are seven net members, with their call letters stored in the A array as follows:

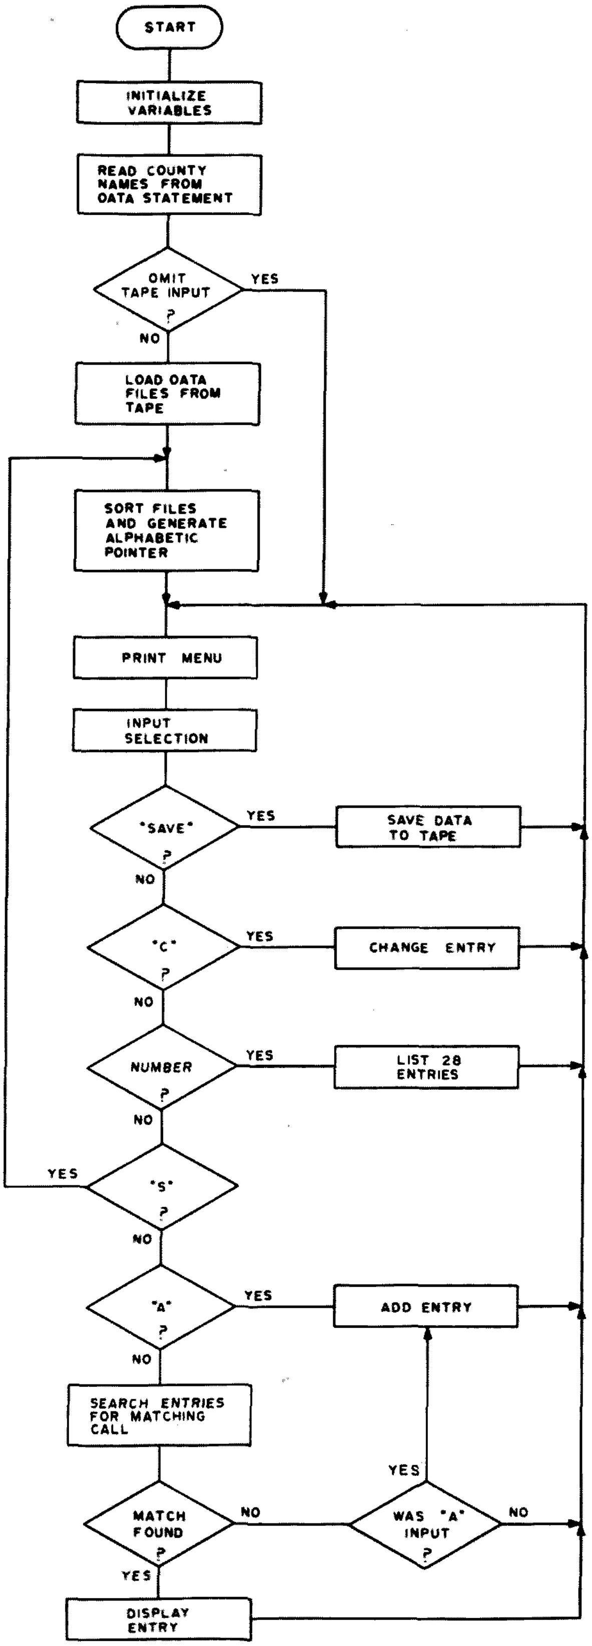

Fig. 1. Flowchart of the ham-radio-net roster.

Program listing.

A(3) W4AFF
A(4) W4GGO
A(5) W4HLK
A(6) W4JXW
A(7) W4JAV

The pointer table is stored in array IA and indicates the alphabetical order of the calls:

IA(1) 3
IA(2) 2
IA(3) 1
IA(4) 4
IA(5) 5
IA(6) 7
IA(7) 6

The first call in alphabetical order is A(IA(1)). Since IA(1) is 3, the call is in A(3), and this is W4AFF. Similarly, the second call, alphabetically, is A(IA(2)), which is A(2), or W4BAA. A search for W4HLK would proceed this way. The first guess is the fourth call in the alphabetical order, or A(IA(4)), which is A(4), or W4GGO. This is too low. The next guess is the sixth in alphabetical order, A(IA(6)), or A(7) which is W4JAV. This is too high. The next guess is the fifth call in alphabetical order. That is A(IA(5)), or A(5) which is W4HLK—the correct call. The call was found on the third try. A list of up to 511 entries can be searched by checking nine entries at most by this method.

Another "trick" to speed up the search process even more compares only one letter of the call at first, then looks at the rest of the call only when necessary. Unfortunately, if we start the comparison (and the original sorting of the data) with the first letter of the call, we will be comparing Ws with Ws so often that no time will be saved. Another solution is to sort the calls initially by the most variable letter position in the call, and search first on that letter position. Then we can take advantage of the time saved by looking first at only one character.

The first character of any call can be only A, K, N, or

W—four possibilities. The second character can be A, B, D, N, or a number. Although that number can be any value from 0 through 9, only one or two are likely to predominate in any given area. That is little improvement over the first character. The third character can be any letter of the alphabet or a number, but numbers—usually one number—will dominate because most calls begin with a two letter prefix (WA, WB, WD, KA, and so on). The fourth character is the best choice. Any alphabetic character is possible and equally likely. In this program, the calls could be sorted by the fourth character and the search carried out first on the fourth character.

Improvements

The most time-consuming part of the program is the Sort routine. It takes about two minutes. Even though it is normally used only during program initialization, a faster routine would be desirable. One possible approach is to use a machine-language subroutine. A much easier approach is to eliminate the sort altogether, and substitute a subroutine that automatically makes the necessary changes in the pointer table whenever you add a new entry or correct an existing entry. Then the pointer table would be saved to tape along with the rest of the data.

Another useful improvement might be the addition of a map with the counties outlined on it to be displayed on the screen whenever you want. Some intriguing possibilities exist for compact storage of such a map in a string variable using the space compression codes—ASCII codes 192-255. ■

Why the Spider™ Antenna?

—the ultimate in mobile antennas

C. F. (Fred) Shmitka, K6AQI
8554 Lurline Avenue
Canoga Park, CA 91306

This antenna is truly amazing. I have operated H.F. mobile off and on for the past thirty years or so, and I thought I enjoyed it. But with the combination of a solid state, no-tune rig and the Spider™ Antenna, hey, it's great! No stopping to change resonators or retune. Just switch the rig from band to band and enjoy your QSO's! I used a matching network at the base of the antenna in the old days, but not with the Spider™. The base impedance on all four bands, 10 through 40 meters, is approximately 50 ohms. Another plus for the Spider™ is that it can be used in many varied and unusual installations, plus mobile on most any vehicle. Mount it on the roof of a house or mobile home; use it for back-packing or civil defense work—any portable use. It can be mounted at ground level, using radials laid out on top of the ground.

There is also a Spider™ Maritimer™ Antenna made especially to withstand the corrosive action of salt water breezes and spray. Mast is non-magnetic stainless steel, the fittings are nickel-chrome plated bronze.

For complete information on the Spider™ Antennas and installation accessories write or call Multi-Band Antennas, 7131 Owensmouth Ave., Suite 463C, Canoga Park, CA 91303. Telephone (213) 341-5460.

The World's Cheapest Modification

All you need to put the FT-101 on 30 meters is three pieces of wire. What could be cheaper than that?

Fred Johnson WB9DDI
307 Walnut Street
Knoxville IL 61448

The new WARC bands present a problem to the owner of an older transceiver. How do you modify the receiver and transmitter circuits to operate on these new amateur bands? New crystals and tuned circuits will be needed to put most rigs on the new bands, but I have found that my trusty old FT-101 needs only three pieces of wire added to be fully operational on the 30-meter (10-MHz) band. This modification should work on the later versions such as the FT-101B, FT-101E, FT-101EE, etc. I have not yet tried it on any of these rigs, but their schematic diagrams are similar and the same modification should work.

The Yaesu FT-101 already has 10-MHz receiving capability built in to allow the operator to check the internal crystal calibrator against WWV. After studying the schematic for some time, I decided that the only things stopping transmission on this band were the lack of tuned circuits in the driver and final plate circuits. Unlike the 11-meter band upon which the rig was designed to operate, the FT-101 was never built to transmit on the 30-meter band. There is no brightly colored jumper wire disabling the transmitter on 30 meters. In fact, there are no connections at all to several of the bandswitch wafers in the 30-meter position.

The outside appearance of the FT-101 remains essentially unchanged. Only the bottom cover plate and internal shield need be removed during the 30-meter modification. The position of all front-panel controls should be as shown after tuning up on 30 meters.

The tuned circuit in the driver plate circuit is gang-tuned with circuits in the driver grid circuit and in the gate circuit of the receiver's first rf transistor (T103, T102, and T101 respectively on the schematic). The front-panel preselector control tunes all of these coils at once by running their ferrite slugs in and out together. Whatever I did to modify the FT-101, I had to maintain the proper tracking of all of these tuned circuits in both the transmitter and receiver sections of the FT-101.

The Driver

In the 10-MHz receive mode, the gate and drain circuits of the first rf transistor are connected to the 20-meter trimmer capacitors. The tuning range of the preselector is such that 10-MHz WWV can be received by running the ferrite slugs further into their coils and resonating the 14-MHz coils at 10 MHz. The FT-101's design made life easy for me in theory. All I had to do was connect the 20-meter and 30-meter band positions together in the transmitter and tune the preselector control for maximum drive.

The tuned circuit (T102) at the drain of the receiver rf stage is diode-switched to the grid of the driver tube during transmit, so no additional modification is needed here. The driver plate circuit (T103) has no connection on 10 MHz, so I had to add a jumper on wafer S1g of the bandswitch from the 20- to the 30-meter positions. The correct lugs to solder to can easily be located by rotating the bandswitch and watching where the wiper points. This operation is simple but requires a soldering iron with a very long thin tip, a pair of long-nose pliers, and the necessary skill to use these tools in tight quarters without burning or melting any important parts. A bright light with a magnifying lens will help tremendously with the modification to the bandswitch throughout this operation. (Bandswitch modifications

are definitely not for cowardly or nervous types.)

The Finals

With the driver stage taken care of, only the pi network (and the FCC) was standing in the way of my 10-MHz signal. I imagined that tying the 30-meter position to the 20-meter bandswitch position on wafer S1m would work here just as it did in the driver section, but for maximum power transfer and harmonic suppression, the coil in the pi network should have an inductance between that for the 40- and 20-meter bands. There were five turns between the 40-meter and 20-meter taps. I guessed and soldered the 30-meter tap on at a point three turns from the existing 40-meter tap. Be very careful to avoid shorting adjacent turns of the coil, as this results in very strange operation on most bands later. (This is the voice of experience speaking!) Pushing down one turn on each side of the new tap's location helps avoid shorting turns. (Yes, those tricks in the handbook really do work.) Since there is considerable rf current at this point, I used a piece of number 14 solid copper wire to connect the new tap to the 30-meter position on the bandswitch.

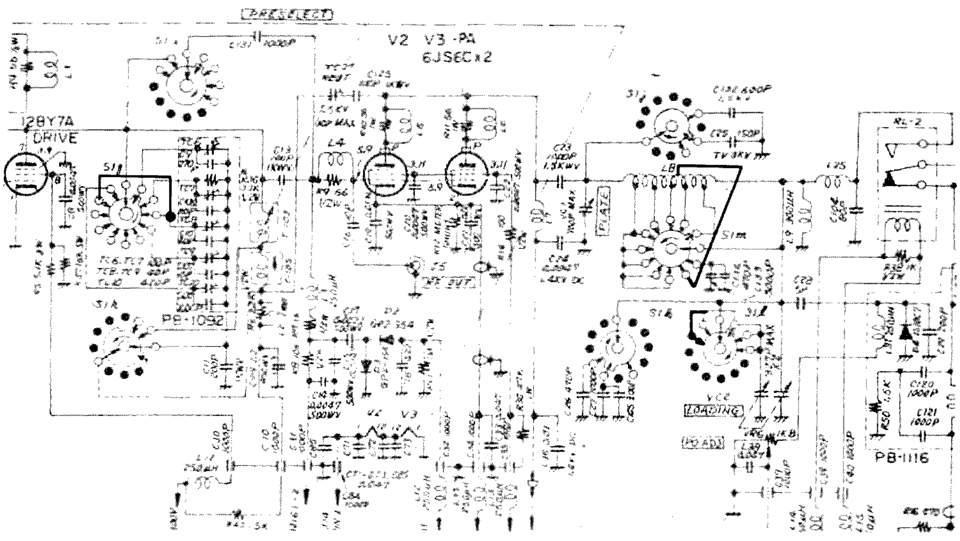

Fig. 1. Schematic diagram from the owner's manual showing the location of the three wires added to allow the FT-101 to transmit on 10 MHz.

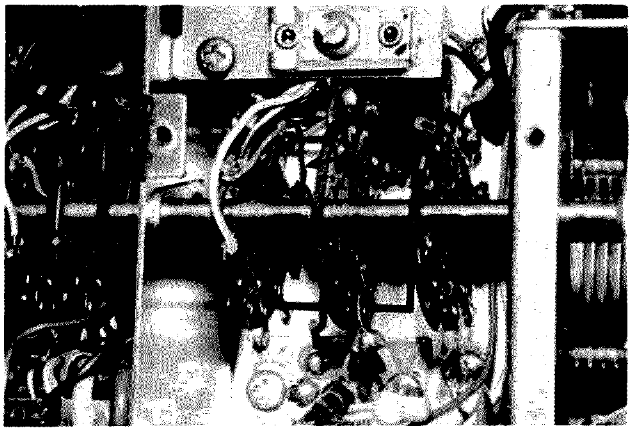
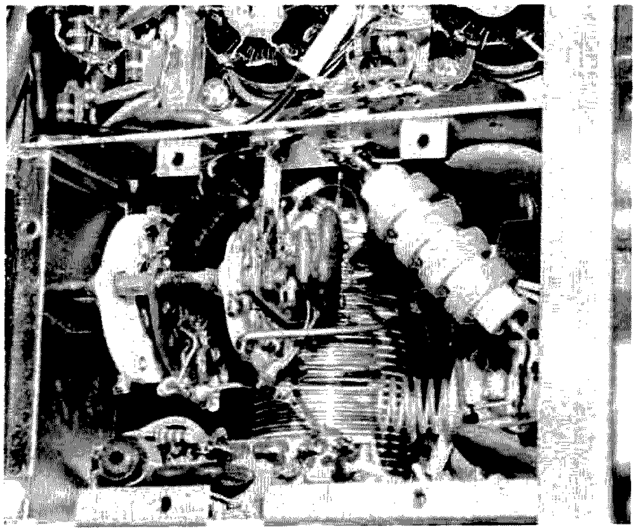
The only other modification needed is to switch in the extra section of the variable loading capacitor. On my particular vintage FT-101, there was not a contact on wafer S1l of the bandswitch at the position that I needed to switch the extra loading capacitor section into the pi network. To get around this problem, I bent a short piece of wire to the shape of a contact. Since the 160-meter band used the extra capacitor section that I needed, I soldered the home-brew wire contact to the 160-meter position adjacent to the new 30-meter position. By carefully shaping and bending this piece of wire, it was made to function as a switch contact on the 30-meter band position. A little TV tuner grease will lengthen the life of this contact considerably.

Results

Testing was performed using a Bird 43 wattmeter and a Heathkit Cantenna dummy load. No change was noted in the performance of the modified FT-101 on any of the existing six bands. I made a comparison of the transmitter operation on the 20- and 30-meter bands. The modified FT-101 produced 125 Watts output for 180 Watts input power (300 mA @ 600 volts) on both bands for an efficiency of 70 percent. The only dif-



The jumper wire from the 20-meter to the 30-meter position on wafer g of the bandswitch is indicated by an arrow in this photograph. Wafer g is located at the front of the driver plate compartment.



Bottom view of PA plate compartment. The home-brew switch contact can be seen on the center wafer, S1l, of the bandswitch. Also seen in this photograph is the heavy wire added from the rear ceramic wafer, S1m, to the new tap on the pi network coil. Since the second harmonic of the 30-meter band is not an amateur band, you will need all the shielding available. Be sure that you replace all of those screws in the PA compartment's bottom shield.

OPTIONAL MOD

An additional modification may be made to the FT-101 which is not necessary to fire it up on 30 meters, but will center the load control while operating on that band.

Without this change, the antenna loading position will be about "2" when tuned for maximum rf output into a 50-Ohm load at 400 mA. However, by adding a fixed 270-300 pF, 500-600-V silver mica capacitor parallel with the variable loading capacitor (VC2), the loading position will move to about "4" or "5" when fully tuned. The capacitor should be added to the 30-meter position of bandswitch wafer S1k which faces the front of the rig.

First, however, a contact must be added to the 30-meter position of the wafer. Remove capacitors C26, C27, and C105 to get a clearer view of the wafer, then inspect the contacts on S1k closely so that you will be able to identify the correct style of contact to mount. The wrong style could result in damage to the rotating wiper of the wafer.

When you know what you are looking for, head for the junk box and find an unused wafer with the proper contacts. Remove a contact from the "donor" wafer by carefully drilling out the rivets that secure the contacts to the wafer. Mount the contact on the 30-meter position of S1k using a small bolt. Make sure that the contact is mounted on the side facing the front of the rig and tighten the bolt securely. Run the switch wiper across the new contact a few times to ensure that they make proper contact, then solder the 270- or 300-pF capacitor between the contact and ground. Don't forget to resolder capacitors C26, C27, and C105 when you are done.

James R. Snyder WØUR
1050 Hawthorn Avenue
Boulder CO 80302

ference noted was that 30-meter operation required slightly more drive. During the tune-up, 180 Watts input were produced on 20 meters with the carrier control set at 6, but when operating on 30 meters, the carrier control had to be advanced to 8 to produce the same 300-mA cathode current indication.

More Bands

The other obvious modification would be to convert the unused (I hope) 11-meter band to the new 18-MHz or 24.5-MHz band. This will require a new crystal 6.02 MHz higher than the bottom edge of the band. In other words, a 30.52-MHz crystal would be needed to operate on the 24.5-MHz band, and a 24.02-MHz crystal to operate on 18 MHz. Since the existing 10/11-meter tuned circuits will probably work fine on 24.5 MHz, only a new crystal should be needed for this band.

If you want to convert the 11-meter band to 18-MHz operation (to get better DX like 20 meters), then the existing tuned circuits cannot be stretched that far and the 15-meter trimmer capacitors will have to be connected to the 11-meter position in all stages of both the transmitter and the receiver. (Sections c, e, g, and m of S1, the bandswitch, will all need this modification.) Adjusting the preselector to a lower frequency should be all that is then needed to be operating on 18 MHz.

Conclusion

With 10-MHz operation now a reality, the modification to get on 30 meters is simple and cheap. Very cheap! Now that the band is opened, let's use it.

Now, let's see, where is that antenna formula? Hmmmm... a bit over 23 feet on each side of a dipole. ■

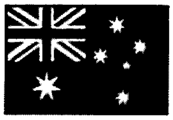
73 INTERNATIONAL

Each month, 73 brings you amateur radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Avery L. Jenkins WB8JLG.*



AUSTRALIA

Jim Joyce VK3YJ
44 Wren Street
Altona 3018, Australia

Perhaps the best way of explaining amateur radio in Australia would be to let you know what frequencies we are allowed to operate on and what our different license classes are.

We have 3 classes of license, the first being a Novice license. To obtain this, you have to pass an exam of 50 multi-choice questions on electronic theory (at a fairly easy level), 30 questions on regulations, and a CW exam at 5 wpm, send and receive. The Novice operators are easily recognized, as they have a 3-letter suffix starting with either N, P, or V, e.g., VK3NOL, POL, VOL. They can operate on phone or CW on the 75m, 15m, or 10m bands.

The next grade is the Limited license. For this you have to sit a much harder exam on theory and regulations, with no CW. This license entitles you to operate on all bands allocated to Australian amateurs above 50 MHz. They also have a 3-letter suffix, starting with X, Y, or Z.

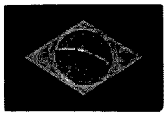
The Full Call on AOCP (Amateur Operators Certificate of Proficiency), sometimes called the Full Call, entitles you to use all bands and modes available to Australian amateurs. The only difference between this license and the Limited license is that you have to sit a CW exam at 10 wpm, send and receive. The suffix for the Full Call is either 2 letters or 3 letters, starting with A, B, C, D, or E.

It has been said that 10 wpm is below the world standard of 12 wpm. But with our exam on CW, we have to send the equivalent of 25 words (averaging five letters per word), in mixed plain language and figures (each figure counting as two letters), in 2½ minutes. More than four incorrect or improperly corrected errors or failure to complete the test in 2½ minutes will result in failure. In the receiving test, you have to receive 50 words (average five letters per word), in mixed plain language and figures (each figure counting as two letters), in 5 minutes. Each figure or letter incorrectly received counts as one error, with a maximum of 3 errors being counted in one word or group of figures. More than 7 errors will result in a failure.

This test, I think, is much harder than having to listen to a text sent in CW at 12 wpm, with no sending involved, when all that is required is that you write a rough draft of what has been sent (and, providing you get a fair gist of the message sent, you pass). Even at 16 wpm, I know which one I would prefer to sit for, but we cannot get the reciprocal licenses in some countries unless we get a 12-wpm endorsement on our license.

Speaking of reciprocal licensing, overseas amateurs visiting Australia for less than 12 months may get a license equivalent to their own home privileges. They also have to adhere strictly to the Australian amateur-radio conditions under which the license is issued. To obtain a license in Australia, you must write to the Superintendent of Regulatory and Licensing in the state you propose to visit, with at least 3 months advance notice prior to your visit.

In the next article, I will start to explain something of what Australia is like, with information on our DX locations.



BRAZIL

Gerson Rissin PY1APS
PO Box 12178 Copacabana
20000 Rio de Janeiro, RJ
Brazil

CB OPERATION ON 28 MHZ

The Brazilian Department of Communications (DENTEL) has been focusing its efforts to find pirate stations using CB equipment to operate at the beginning of the 10-meter CW band.

The CB band ends at 27.605 MHz, but they use modified equipment to extend their operations as far as 28.1 MHz. In this way, it is very difficult to have a QSO on 10-meter CW, especially during the weekends. We can hear pirates from a few countries in South America as well as from Europe.

All Brazilian CW groups are encouraging their members to use the 10-meter band as much as possible and banish the pirates.

ONE MORE BRAZILIAN BEACON

For propagation purposes, the Brazilian Amateur Radio League/Department of Americana, in the state of Sao Paulo, has constructed a QRP beacon with 10 Watts output on 28.300 MHz. Carlos PY2VRX, Roberto PY2FUZ, and D'Orssay PY2CRI all assisted in establishing the transmitter.

The station is already on the air, with the callsign PY2AMI, and transmits the following message: VVV DE PY2AMI PWR 10W ANT GP LAT 22 45 S LONG 47 16 W AMERICANA SAO PAULO. Any report or QSL may be sent to PY2AMI, Beacon Project, PO Box 31, 13470 Americana, SP, Brazil.

10-MHZ BAND

Brazilian amateurs are not yet allowed to use the 10-MHz band. Most of them have already bought new equipment using the WARC bands, but the authorities are still studying the treaty.

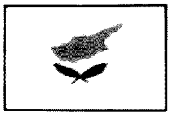
GPCW AWARD

Sponsored by the Grupo Praiano de CW, the GPCW Award is available to all licensed amateurs for confirmed contacts with three GPCW members.

Contacts must have been made after November 5, 1973, on any amateur band. Only 2-way CW contacts with a minimum RST of 338 are allowed. No QSL is necessary.

Send a list of stations worked (call, date, time, band, mode, and report) and 5 IRCs for mailing expenses to GPCW, PO Box 556, 11100 Santos, SP, Brazil.

GPCW members are: PR7CM, PS8AUJ, PT8AVV, PY1AFA, PY1CMS, PY1DG, PY2ARX, PY2BBQ, PY2BKT, PY2BOP, PY2CAR, PY2CE, PY2CJW, PY2CZL, PY2DBU, PY2DCP, PY2DHP, PY2DV, PY2DYX, PY2ESW, PY2ETW, PY2EW, PY2EYF, PY2FDO, PY2FHC, PY2FK, PY2FNB, PY2FNE, PY2FRW, PY2GCP, PY2HAB, PY2HAF, PY2IBH, PY2IEG, PY2IEM, PY2JN, PY2KL, PY2OIL, PY2OIN, PY2ORF, PY2RAD, PY2RAN, PY2RRG, PY2SCR, PY2SFI, PY2SLS, PY2TT, PY2TUE, PY2UGR, PY2US, PY2VFA, PY2ZEB, PY2ZV, PY3BU, PY3CJI, PY4ETW, PY5CMS, PY6WF, PY7BOS, PY8BI, PY9AY, F6HSX, and CT1CFG.



CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol, Cyprus

BEACONS IN CYPRUS

For many years, the Cyprus Amateur Radio Society has been running experimental transmitters as beacons for the study of radio-wave propagation.

At the moment, there are three beacons in operation:

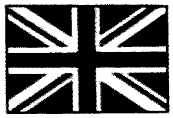
a) *28.220 MHz*—This beacon is used for the study of shortwave propagation and transmits the call 5B4CY. This beacon is watched by many amateurs throughout the world who often send reports or QSL cards with information about the reception of its signal. The power of this beacon is 15 to 20 W and the antenna is a quarter-wave vertical on the ground with lots of radials under the soil.

b) *50.5 MHz*—A transmitter on this frequency aids the study of many phenomena such as sporadic-E and TEP (Trans-equatorial Propagation), and during the period of maximum sunspot activity, it was heard in all continents. The transmitter was home-brewed by 5B4AZ and has an output of 15 W and a ground-plane antenna.

c) *70.11 MHz*—This beacon is also used for sporadic-E and TEP studies and has been heard in Europe and South Africa. The transmitter was donated to CARS by G4BPY, whom the Cyprus amateurs would like to thank very much for his most useful and generous offer. We do hope that other amateurs will help our society in other fields. Because of its small size, it is running on a shoestring and every little bit of help is greatly appreciated. The 70.11-MHz beacon gives 15 W, and the antenna is a 4-element yagi beaming to Europe between May and August and beaming to South Africa the rest of the time.

All beacons are located at Zyghi at the site of the BBC relay station, and they all transmit the callsign 5B4CY.

The beacon keeper is Nick 5B4AZ and all reports of 5B4CY should be sent to him.



GIBRALTAR

Jimmy Bruzon ZB2BL
27/2 Flat Bastion Road
Gibraltar

On June 18, the 1st Battalion, The Duke of Wellington's Regiment, celebrated the 168th anniversary of the Battle of Waterloo, and to mark the occasion, an open day was held at Lathbury Barracks where the Gibraltar Services Amateur Radio Club set up an amateur-radio station using the callsign ZB2DWR. Unfortunately, due to poor conditions and the fact that the date coincided with some contest, not too many stations were worked. The station was operated by Iain Morris ZB2HC and Peter Green ZB2HM. QSL information is either via the Bureau or to PO Box 292, Gibraltar.

Another bit of news was the first-ever two-way QSO on 6 meters between Gibraltar and the United Kingdom. This took place on May 6, when Ken G5KW and I managed to work each other, first on CW and then on SSB. Ken has been doing quite extensive monitoring of the ZB2VHF 6-meter beacon. For those of you who are also operational on 6 meters, the ZB2VHF 6-meter-beacon frequency is 50.035 MHz, running 30 Watts to a 5-element yagi. Reception reports are most welcome and should be mailed to me via the Bureau or, preferably, to my home address.

The oldest licensed amateur still resident on the Rock is Gordon Black ZB2J. Gordon's interest in amateur radio was aroused through ZB2A, the RAF Amateur Radio Club, back in 1948. Of course, home-brewing was the in thing in those days; the RAF Amateur Radio Club station consisted of a couple of T-1131 transmitters, AR-88 and HRO receivers, and other bits and pieces of wartime equipment. Some time later, Gordon and some of his work-mates at the Royal Navy wireless station decided to form the Royal Navy Amateur Radio Club. Through their Commanding Officer, they applied for a club callsign and were issued ZB2G. The RN Amateur Radio Club was active for a number of years on 7, 14, and 28 MHz, and in those days, there was stacks of room to operate in, so receiver selectivity was not necessary. All one had to do was to QSY some kHz up or down the band and find a clear spot to operate on.

In 1950, Gordon decided it was about time he got his own ticket, so after sitting the RAE and CW test, he was issued callsign ZB2J. He then constructed his own receiver and transmitter which he used until he got posted to the UK. While in Wales, Gordon was issued the callsign GW3HIJ, and since the rigs were far from portable in those days, it was a matter of home-brewing once again. From Wales, Gordon operated on CW for a couple of years until he got posted, and then came a period of inactivity.

In 1955, Gordon returned to Gibraltar and re-applied for his ZB2 call. He was active mostly on CW until 1964-65 when he joined the Gibraltar Broadcasting Corporation. With work taking up most of his time, ZB2J was inactive until 1979.

The days of home-brewing were now over, and since the idea of playing around

Gordon ZB2J operating his station. Note the home-built ATU on top of the TS-520.

with a soldering iron and voltmeter at home didn't appeal to him any more (having been Chief Engineer for the Gibraltar Broadcasting Corporation for a number of years), he decided to get a TS-520, which forms part of his present setup. The antennas are a 10-meter dipole, a 20- and 15-meter dipole on a single feeder, and a longwire for 40 meters. He eventually intends to get a beam antenna, possibly some compact triband beam.

Gordon is active just about every morning and most evenings on 20 meters; he prefers operating on 15 or 10 meters when it's open. Being a rag-chewer, he prefers to keep away from those "my-name-is-Gordon-you're-RST-599-please-QSL" style QSOs. Gordon has worked about 180 countries, though he admits he is not a wallpaper collector. His QTH is located on the west side of the Rock; from there he has a very good take-off towards the southwest, west, and north.

Though Gordon does not enjoy contest operating, he does enjoy working DX stations and adding new countries to his collection. At present he is the General Manager of the Gibraltar Broadcasting Corporation.

Next month we shall be visiting John ZB2AT. John is also the license-holder for the 1st/4th Scout Group ZB2FFG.

Currently, the Gibraltar Amateur Radio Society is experiencing some TVI problems. However, as soon as that's sorted out, ZB2BU shall be active on 10, 15, and 20 meters. The GARS meets on Tuesday evenings and if all goes well, I shall be able to provide you with more details next month.

Best 73 es CU next month, or perhaps work you before then.

THE UK SCENE

Those of you awaiting QSL cards for recent contacts with G2MT probably do not appreciate the historical significance of that call.

Some sixty years ago, the callsign 2MT was used to introduce the first scheduled entertainment broadcasting in the United Kingdom. Recently, the Home Office (the then-regulatory authority for amateur radio in the UK) approved the use of G2MT by the Marconi Radio Society, whose members are drawn from the employees of Marconi Space and Defence Systems Ltd. in North London.

The station will operate from the Stanmore headquarters of the Marconi Radio Society, but bands and operating schedules are subject to prevailing propagation conditions.

At the time of this writing, we are well into the summer mobile rally calendar with two or three events each weekend. (Even though the English summer sometimes lasts only a week or two, the rallies are held resolutely through October!)

On a slightly smaller scale than, say, the Dayton Hamvention, mobile rallies are very popular over here and are characterized by big crowds, warm beer, and curly sandwiches.

Local events often are held in school or social halls with only a handful of regular trade stalls; filling the remaining space are weekend traders and tables rented by individuals.

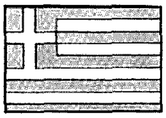
Regional events attract more traders who exhibit their full range of Japanese black boxes. Unfortunately, these invariably remain in their shrink-wrap protective covers and no facilities exist for demonstrations (any operating station is usually being provided by a local club). It never ceases to amaze me that fellow hams will part with vast sums of money (a Yaesu FT-One currently retails here at about $2200) for equipment chosen in these conditions.

Far better to visit one's local store as I do occasionally. Not only do I get to try any gear in which I am interested, but I also get a cup of coffee and a chat with Peter G4KKN (who runs the local Amateur Radio Exchange).

Despite all this, mobile rallies can be fun—particularly listening to the talk-in channel whilst approaching. I recently heard a ham three times do the opposite of the instructions given him and then wonder why he remained lost.

A big complaint against mobile rallies is that they occupy the OM on a Sunday and provide little if any attraction for the family. In one event, at least, this is not so. The RSGB National Mobile Rally is held at Woburn Abbey, seat of the Marquis of Tavistock. Surrounded by beautiful parkland, the house alone is worth a visit, but the intrepid can always take in the wildlife game reserve.

The RSGB's advertising for this event highlights the many side attractions of Woburn but fails to mention the area's most interesting sideline—Woburn Golf Course, home of the Masters and other tournaments. Perhaps the organizers do not share my interest in golf.



GREECE

Manos Darkadakis SV1IW
Box 3751
Athens, Greece

This month's column will bring you all the necessary information for getting an SV license while in Greece. (See box.) At the moment, reciprocity agreements exist with the US, Canada, and Cyprus. Therefore, only amateurs from these three countries can obtain an SV call during their stay in our country.

Please note that for the first category the minimum requested time for the issue of the license is 3 to 4 weeks, and it is 3 months for the second. Therefore, applicants must apply in advance of that time.

Lately, many efforts have been directed toward the establishment of a guest license in Greece. This one will be valid for a maximum of three months and will be available to every licensed amateur worldwide. Anyway, we will be back with more details after the agreement.

INSTRUCTIONS FOR FOREIGN AMATEUR-RADIO OPERATORS
(Legislative Decree 1244/72
Official Gazette 181/A/16 Oct 72)

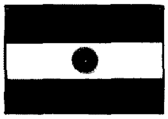
Foreign amateur-radio operators who are citizens of countries having a reciprocal agreement with Greece may operate amateur-radio stations in Greece if they submit an application with the following supporting documents to the: Ministry of Communications, General Directorate of Posts and Telecommunications, Directorate of Radio Communications Control, Section III, 49 Leoforos Syngrou, Athens, Greece.

1) Amateur-radio operators who wish to operate stations in Greece for less than one year must submit:
- a) An application giving full personal identification data, the intended location of the radio station, and the point and manner of entry of the radio equipment into Greece.
- b) A photocopy of the amateur-radio license notarized by the appropriate government agency or amateur-radio club of the applicant's home country. If the license has no expiration date, the applicant must provide a certification by the appropriate government agency or amateur-radio club in his home country that the license is still valid.
- c) Technical characteristics of the radio station.

The above documents must be submitted to the Ministry before a permit to operate is granted. This will be valid for a period equal to the applicant's intended stay in Greece, not to exceed one year, and will not be renewable.

2) Amateur-radio operators residing permanently in Greece must submit:
- a) An application bearing a 10-Drachma revenue stamp.
- b) Identification data.
- c) A photocopy of the amateur-radio license notarized by the appropriate government agency or amateur-radio club of the applicant's home country.
- d) Technical characteristics of the station.
- e) A document showing the applicant's membership in the Greek Amateur Radio Club.
- f) A 300-Drachma fee.
- g) A 50-Drachma revenue stamp.

The permit will be valid for two years and will be renewable. Amateur-radio operators in this category are entitled to transmit using the output wattage permitted by their license, but not to exceed 300 Watts PEP.



INDIA

James Kalassery VU2ARL
PO Box 1446
36/677 Monastery Road
Cochin 682 011, India

Under the 1978 Indian Wireless Telegraph (Amateur Service) Rules which are currently in force, we have four categories of licenses—Advanced, Grade I, Grade II, and Grade II (VHF).

Grade II and Grade I are available to anyone who is at least 14 and 16 years old respectively and has passed the respective Amateur Station Operator's Certificate (ASOC) examination. However, an Advanced ASOC examination can be taken only by those who have held a Grade I license for 2 years or a Grade II license for 3 years. Morse-code requirements are the same (12 wpm) for both Grade I and Advanced licenses, and therefore Grade I amateurs need pass only the theory portion of the Advanced ASOC examination, which is of a slightly higher standard, to qualify for the Advanced license. Those who do not qualify in the Morse-code test (5 wpm) of the regular Grade II ASOC examination can get the Grade II (VHF) license, which will permit them operation on 2-meter phone.

Out of the around 1800 amateurs in India, only about 30 are Advanced licensees; almost the same number hold the Grade II (VHF) license. The rest of the ham community is almost equally divided among Grade I and Grade II.

The largest representative body of radio amateurs in India is the Federation of Amateur Radio Societies of India (FARSI), which has more than 60 affiliate clubs and a total membership well over 1000. Most of these clubs are in cities, but some smaller towns also have very active clubs. The largest affiliate is the Radio and Electronic Society of India (RESI), followed by Madras Amateur Radio Society (MARS)

and Kerala Amateur Radio League (KARL). Many clubs conduct regular classes, assisting candidates preparing for the ASOC examinations. Being World Communications Year, more and more clubs are being formed and affiliated with FARSI this year.

One of the main projects of FARSI is the All-India Convention held every three years. The last one was held in Bombay in 1981 and the next one is expected to be held soon. FARSI also publishes a monthly journal, *Radio*, which is sent free to the members of all affiliate clubs.

With the arrival of many more rigs imported under the Open General License of the Import Policy, more and more Indian amateurs are now being heard on the bands, which means more QSOs and more QSLs. To take care of the flow of these cards, FARSI runs a well-managed QSL Bureau (PO Box 6538, Bombay 400 026), which serves all radio amateurs in India, irrespective of their membership.

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office 85530
Israel

VHF IN ISRAEL

One of the most popular aspects of ham radio in Israel today is VHF operation—more specifically, two-meter FM. Please note: We do not have a code-free VHF class of license here, so those operating on VHF also have full HF privileges. Thus, Israelis chose two meters on its own merits alone.

Although the widespread use of these shorter wavelengths has occurred here only in the last decade, it would be wrong to assume that the world above 30 MHz was unknown until the early '70s. In the last yearbook of the Israel Amateur Radio Club, we see a couple of snapshots of Bruno 4X4DH taken on a field day in 1965 at Kibbutz Sasa in the mountains of the Upper Galilee. The first one shows him raising a two-meter yagi on the kibbutz's water tower, and the second depicts him crouched over an SCR-522 making the first contact between Sasa and Haifa. A year earlier, in 1964, Bruno had made news by being the first amateur to make satellite contact between Europe and Asia via OSCAR 3. Bruno also had received the signals of pioneer OSCAR 1 transmitting its famous HI beacon.

The real boom in VHF happened in the spring of 1974 when the police department decided to update its communications equipment. The Ministry of Communications, perhaps because of the prompting of a few hams holding key posts there, deemed that the equipment being retired was unfit for commercial use. This left only one possible area for the release of the gear—the radio hams!

So, for a small fee you became the proud possessor of a Motorola D43GGV high-band FM transceiver, sporting about thirty tubes, including a 6146 final. If you were fortunate, you had an ac supply built in—otherwise you had to deal with a real humdinger of a 12-volt vibrator.

The other item made available to the ham population was the Japan Radio Corporation hand-held FM transceiver. This was a real beaut—totally solid state, dual channel, although about 2½ times the volume of today's hand-helds. You may recall that we then called such units "bricks." I don't remember what these cost us, but the Ministry did give a few of these free of charge to club stations.

Well, through the Israel Amateur Radio Club, a bulk order of crystals was made from Tadiran, Israel Electronic Industries, and two meters came to life! People were having a ball, tasting the joys of this new mode of communications. There we all were on 145.725, thinking that this intercom party line was great, not knowing that bigger and better things were just around the corner.

A few of the boys in Beersheva took a Motorola GGV and turned it into a primitive repeater, Israel's first. The next issue of *HaGal* (The Wave), the IARC periodical, came out with a band plan, allocating repeater and simplex frequencies for the various cities and districts. This was based on the European scheme with 25-kHz spacing between channels—145.000 to 145.225 being the repeater uplinks for R0 to R9, and 145.250 to 145.575 being simplex channels S10 to S23. Of course, 145.600 to 145.825 are the repeater outputs going from R0 to R9—standard 600-kHz splits. (R8 and R9 have been dropped in the last couple of years to accommodate amateur satellites as per the IARU band plan.)

Your correspondent, living in the Negev, had been content to chit-chat on the Beersheva frequency with his GGV, occasionally making a DX contact with the Tel Aviv repeater on the other crystal channel when tropo ducting permitted. One day, I visited a nearby ham who had a synthesized rig, and I was astounded to hear the Haifa repeater 250 km north of here coming in full quieting. I was hooked, and by January, 1979, I had purchased a scanning transceiver.

This was indeed the time of the real two-meter boom here—people had had a lot of fun with the "junk" rigs and were now buying commercial synthesized gear. The repeater and simplex channels were buzzing day and night. By virtue of a few amateurs holding key positions in Motorola Israel, retired repeaters and duplexers were donated to the IARC, and at this time, there are five two-meter machines in operation (R0—Haifa, R1—Jerusalem, R3—the Galilee, R5—Beersheva, and R7—Tel Aviv) and one 70-cm repeater in the center of the country.

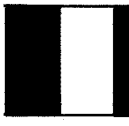
Israel, located on the Mediterranean coast and having frequent high-pressure weather systems, is a VHFer's paradise. All summer long (6 months!) there is tropospheric ducting, making long-range contacts commonplace and two-meter QSOs with Cyprus a regular affair. Sometimes sporadic E appears, and on FM I've worked into Greece, Italy, and Yugoslavia and have heard Hungary. Of course, the serious two-meter DXers are on CW and SSB around 144.300, and some have contacted England. But for us run-of-the-mill FMers, this DX is really the icing on the cake.

Two meters has really changed the face of Israeli ham radio almost beyond recognition. Some sneaky fellows have lent their two-meter gear to "retired" oldtimers and have thus rekindled their fire, getting them back on the air. Previously, the only local meeting ground was 40 meters for a few hours on the Sabbath, but now hams in the country are in touch with each other all week long at all hours. For better or for worse, the hams now are acquainted with each other very well, and Israeli hamdom has become a kind of village!

The repeaters are now less active than they were a year or two ago. It seems that either the novelty has worn off or the long roundtables have talked themselves out. Still, I suspect, just as many people are monitoring—it's simply that they don't reach for the microphone as often.

Every time Shimshon 4X4GF, "Gefilte Fish," meets a new operator on two meters, he enters him into his list and tells him what number station he is that he's worked on the band. The last time I heard, he had just passed the 380 mark, definitely deserving a place on the Honor Roll!

Visiting amateurs are always very welcome on our straight carrier-access repeaters. Should you be coming here, by all means bring along that portable rig. It will add another warm human dimension to your trip to Israel. Reciprocal licensing is no problem, and details may be found in my column in the June, 1983, issue of *73*.



ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
21029 Milano, Italy

RECIPROCITY IN ITALY

In accordance with the Telecommunications Act of March 29, 1973, foreigners are granted permits for short visits and station licenses for longer stays in Italy. A temporary permit is granted for a maximum of three months, and it cannot be extended. However, a foreigner can submit a new application in order to obtain another permit, although consecutive permits will not be granted for more than a 12-month period.

Any foreigner who intends to stay in Italy for more than one year must first register his residence. Then he can request that his amateur license be converted into an Italian operating license, which will then be granted in the same way that Italian nationals receive theirs.

Applications sent from abroad may be written on plain paper, while applications from Italy must be on revenue-stamped paper. All must be filled out in Italian and accompanied by a 3000-lira revenue stamp and an additional 2100 lira for postage. IRCs may be substituted at an exchange rate of about 500 lira per coupon. In addition, the license granted in the country of origin must be valid for the entire period of the Italian temporary permit.

Notes

A photocopy of the station license must be mailed with the application, and I recommend that you post the envelope as a registered letter. For overseas airmail service, add 3700 lira, and if the application is handled through the reciprocal licensing department of the ARI, only $8 US is required to cover expenses.

It is advisable to apply for a temporary permit at least 45-50 days prior to the expected date of arrival in Italy.

You must also pay a fee of 2000 lira at any post office when you fill out the form attached to the permit. Prior to payment, fill out the front sides, and on the back write "Canone per l'autorizzazione temporanea rilasciata a cittadino straniero per l'impianto e l'esercizio di una stazione di radioamatore in Italia" (Art. N; 331 D.P.R. 156 del 29/3/73).

The postal address of the licensing administration is: Ministero Delle Poste E Delle Telecomunicazioni, Direzione Centrale dei Servizi Radioelettrici, Divisione 5 Sezione 3, Viale Europa 160, 00100 Roma. The telephone number is: International + 39 6 54601, extension 4975. All correspondence and calls should be in Italian.

The address of the reciprocal licensing department of the ARI is: ARI-R.L.D., Via Giorgione 16, att. Manuel F. Caiero I4CMF, 40133 Bologna. The telephone number is: International + 39 51 389502. Phone calls are answered in English, French, or Spanish after 8 am GMT, except weekends.

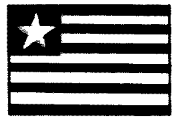
Here are instructions on how to fill out the application form:

1) When you fill out the form, please remember that mobile operation is allowed only on VHF and UHF.

2) Indicate the manufacturer and model number of your equipment. The input must not exceed 300 W.

3) It is very convenient to apply to the reciprocal licensing department of the ARI, since they will take care of many of the administrative details.

4) If you do any travel in Europe, it is worthwhile to purchase *The International VHF-FM Guide*, by J. Baldwin G3UHK, 41 Castle Drive, Maidenhead, Berks SL6 6DB, Great Britain. The book contains lots of useful information regarding VHF and UHF repeaters all over Europe. It also provides the addresses of various postal administration offices in Europe and procedures for obtaining temporary licenses. The cost of the book is $3 US, plus postage, and the editor's phone number is: International + 44 628 37837.



LIBERIA

Brother "Don" Donard, Steffes, C.S.C.
EL2AL/WB8HFY
Brothers of the Holy Cross
St. Patrick High School
PO Box 1005
Monrovia, Republic of Liberia

Liberia amateur radio, when the truth is out, is primarily expatriate amateur radio. Missionaries, doctors, teachers, and even business people like to have an amateur-radio license so that they can talk to their friends and relatives back home. When they travel, they like to pass on information regarding airplane schedules, arrival times, and things like that.

There are many of these people in Liberia. To say that they number in the hundreds is conservative. Not all of them have radios, but as it works out, there are more expatriates operating amateur radios than there are natives. This is not a desirable situation, and we in the Liberia Radio Amateur Association are trying to do something about it.

The point of this article is to discuss amateur radio in Liberia in its relation to medicine. There are a few major cities in Liberia that have hospitals, doctors, and other medical facilities. People who can reach these places can be cared for, but the greater part of the population lives in villages where there may be no communication, difficult transportation, and no doctors or medical facilities. Some of these villages are served by medical missionaries who operate mobile clinics, and some of them are not served at all.

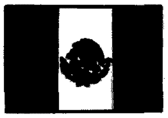
One day, I was turning the dial on my radio when I heard a call come in from one of these outlying areas. The amateur up there was in communication with a doctor, an amateur, here in Monrovia. He was describing severe leg infection which could involve the loss of the limb. The doc-

tor stated simply that the patient would have to go to a hospital. The answer came back—there isn't any. The next suggestion—he must see a doctor; again the answer—it is out of the question, the nearest doctor is forty miles away and there is no way of getting there.

Running out of alternatives, the doctor here in Monrovia began to ask detailed questions about the situation and to prescribe over the air. A schedule was set for 24 hours later at which time a decision had to be made as to whether or not the infected area would be lanced.

Medical consultation on amateur radio is common here. Many times there are emergencies where this medium is the only communication available. Some weeks ago, I received a frantic call from an amateur in the vicinity of one of the leper colonies. They were out of a medicine which the lepers must have on a regular basis to hold the disease in check. I drove downtown to bring the message to the leprosy control center.

We, the amateurs, lack numbers. We have other commitments; radio is a hobby. So, it is difficult, but we are trying to set up a network of communications (the Liberian Net) which will operate on a regular, daily basis. As we expand our numbers and equipment, we may make this a reality.



MEXICO

Mark K. Toutjian XE1MKT
Apartado Postal 42-048
06470—Mexico, D.F.

Since Mexico borders with the United States and has a lot of tourist attractions in all of its 32 states, many questions have come up in the minds of our fellow hams from outside the country with regards to regulations here, happenings, and anything to do with radio-wave activity from down "south of the border." I hope to answer some of these questions one by one as a correspondent for *73*. Some have asked about what awards are offered here. Let's take a peek at one of these awards this month.

THE MEXICO CERTIFICATE

Well, one of the unique awards that the Mexican Radio Experimenters League offers to hams around the world is the Mexico Certificate or diploma, with the following requirements.

1) Confirm at least 50 Mexican stations; anything from January 1, 1957, on is accepted.

2) Confirm 15 different states within Mexico, including what we call "D.F" (Mexico City). (See box.)

3) Stations confirmed should be legally authorized by the Secretary of Communications and Transports (SCT).

4) Combining CW and phone is not accepted, although either of the two is OK as are SSTV and RTTY.

5) Your registered correspondence should be sent to La Liga Mexicana de Radio Experimentadores, A.C., PO Box 907, 06000 Mexico, D.F.

6) The Mexican ham operators who apply for this award have to confirm bilateral contacts with at least 20 different states besides Mexico City.

7) You should include with your application the confirmed QSL cards, the corresponding list, and $3.00 US for postage and handling. Don't forget, CW, AM, SSB, RTTY, and SSTV are accepted.

There are quite a few other awards that are available through our Radio Experimenters League here in Mexico and from different radio clubs; I will deal with them in future columns.

Personal satisfaction can be derived through obtaining one of these awards, since time and experience as a radio operator is obviously a factor. Part of the etiquette of the Mexican ham operator is the importance for one to be balanced, not letting the radio control your daily activities; rather you should control the rig so that it doesn't push aside the more important things in life. I, personally, live by that standard. That's the good thing about obtaining awards now and then. You're not pressed for time in order to obtain them. You can take your sweet time (days, weeks, or even years) and eventually begin framing those lovely certificates. And, of course, your ability to work "over the air" and set up your antennas and equipment in emergency situations should improve as time goes on.

So, try for the Mexico Award! Get started soon! And for those of you who already have some QSLs saved up from Mexico, work on the states you lack still, and happy DXing!

The Netherlands

A TEMPORARY LICENSE IN HOLLAND

When you're planning a visit to the Netherlands and would like to talk to the Dutch amateurs, you'll need a license for it. I will give you all some tips:

The application for a temporary amateur-radio license must be sent to Holland at least six weeks in advance of the date that you desire the license to be used. For the application form that you'll have to fill in and a copy of the Dutch amateur-radio license conditions, send your request to: Radio Control Services, PO Box 570, 9700 AN Groningen, The Netherlands.

Remember, too, that the Dutch Radio Control Services will not deal with any license requests before you have paid the annual charge of D. fls. 65-- (about $20.00) in advance. Unfortunately, you have to pay for a whole year even if you only stay for a week or so. Furthermore, your payment can only be made by International Money Order addressed to: P.T.T. Centrale Dienst, Kortenaerkade 12, 2518 AX The Hague, The Netherlands.

Note that your callsign must be stated on your money order.

Together with your application form, you have to send a verified photostat copy of your license and a copy of your money order. The copy of your license must be verified by your postal service or the authorities that deal with licenses in your country. There must be a clear indication on your license that it is still valid.

To be granted an amateur-radio license in The Netherlands, you have to be at the age of sixteen or over.

The license conditions, as you know, vary from country to country. For Holland, they are gathered in a small 39-page booklet in the English language that you'll receive together with your application form. When you open this booklet, you'll find out that 50 and 220 MHz are not amateur frequencies in Holland. Licenses for those bands are very rarely given.

Other things that are not allowed in Holland are:

a) The use of transmitters in aircraft.

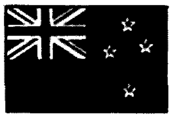
b) The transmission of messages from third parties.

c) The transmission of messages of a commercial nature.

It is interesting to know that most of the Dutch amateurs on 2 meters use horizontally-polarized antennas at their QTHs, while most of the mobile stations and repeaters use verticals.

When you arrive at Schiphol Airport (Amsterdam), give a shout on the nearest repeater there: PI3HLM on 145.775 MHz. Almost all Dutch amateurs speak English in some way and they will be glad to hear you and will answer any question you'll ask them. If you have a bit of luck, you will find a YL or an OM who will show you around the beautiful city of Amsterdam—the museums, buildings, etc. If you are in for a romantic trip, take a boat trip through the canals of Amsterdam at night!

So, if you are planning a trip to Amsterdam, there are reasons enough to bring your HT along. Don't forget fresh batteries (Hi).



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier, New Zealand

Kia Ora atu i Aotearoa! (Hello from New Zealand.) This month I will continue with the special groups within the New Zealand Association of Radio Transmitters; I shall cover the OTC, the Old-Timer's Club, New Zealand's equivalent of the QCWA in the USA.

The formation of the Old-Timer's Club was approved at the 1952 Annual Conference of NZART at Dunedin. During the ensuing year, the old-timers throughout the country worked towards the inaugural meeting of the group to be held during the 1953 Annual Conference of the Association at Palmerston North.

The first meeting was duly held at 1940 NZTima on May 31, 1953, in a convenient room, after the conference sessions were finished. Sixteen eligible "old hams" attended and had discussions on the proposed objectives of the club and the conditions of eligibility for joining the club. The following was decided and remains applicable today, 30 years later.

Membership is available to any ZL amateur who has held an amateur license for the last 25 years or more and is still an active amateur.

The objectives of the Old-Timer's Club (ZL) as set out in its constitution adopted in 1954 are as follows:

(i) To recognize service to amateur radio.
(ii) To revive and maintain interests and good fellowship among the older members in the common cause.
(iii) To offer aid to the "young-timers."

Within the first three months, the numbers of the OTC had grown to 55, and they all were issued with Certificates of Membership on September 30, 1953, and all deemed to be foundation members of the club. The certificates were donated by two old listener members, Monty and Old Fred, and were designed by one of the members.

The OTC has continued to flourish. Today it has over 500 members, 150 who have received their 50-year certificates and one his 60-year certificate. The club meets regularly "on the air" in OTC Nets on 80 and 40 meters on Sunday mornings. Eyeball QSOs also are maintained in the main cities, where old-timers get together during the afternoon for meetings or on the weekends during the summer for picnic outings. The Old-Timer's Club has its Annual Meeting and Reunion during the NZART Annual Conference each year, when they elect their president, the Grand Old Man, who holds office for one year.

There is no set subscription or entry fee for membership, but any small donations made with applications for membership do assist with the club's expenses for postage and stationery. Also, there is usually a collection made at the club's annual meeting each year to supplement the finances.

The OTC also has a regular column in the Association's magazine, *Break-In*, and offers an award, the Old-Timer's Cup, to the elected Grand Old Man each year. A certificate in keeping with this grand office is presented to the holder of the cup as a permanent reminder of his year in office. The Montgomery Cup, another OTC award, is presented to the member or members who have contributed the most worthy item or article to *Break-In* each year.

Recently, the OTC published a Directory of Members containing the names of all members at the date of publication, along with other relevant information such as present call, radio name, original call, other calls held, year first licensed, QTH, and OTC number. The Directory is available to interested overseas amateurs by writing to the Secretary, OTC—G. E. Brown ZL2BD, 35 Chamberlain Street, Nelson, New Zealand, enclosing US$3.00 or 12 IRCs, which includes return postage.

BITS 'N' PIECES

OTC Diamond Jubilee operators, Dan Wilkinson ZL2AB and Len Spackman ZL1AC, are joined by another two old-timers who also celebrate 60 years of ham radio this year. They are George Blake ZL3FX and Bob Robinson ZL4AC. Congratulations, George and Bob, on joining that elite corps of 60-year operators! Also two honorary OTC members have achieved

A Two-Tone Squelch to Solve Your Scanner Woes

Selective listening is the key to success. This squelch will help you cut the chatter.

If you're like me and listen to a scanning monitor much of the time that you're at home, then you probably have the same problem I've had: The monitor either drowns out the wife and kids or the family retaliates, turning up the TV and winning the battle of Television vs. Scanner.

Go ahead—try to explain to your wife how important it is for you to hear the location of that fire or ambulance call if you're a volunteer fireman or paramedic. Or tell her that you're waiting for a call on the local amateur repeater. You'll probably agree with me that you need more than an explanation. I figured I needed a quick and dirty sequential tone squelch to silence the "10-21 or furnish a number" and "QTH is Pine Grove and the rig is an Icom 2-AT" that filled the scanner's speaker.

I'm not an engineer and I wasn't about to re-invent the wheel or the tone squelch. Instead, I searched through back issues of *QST, Ham Radio,* and *73* looking for an easy-to-build two-tone sequential squelch. The closest circuit I could find appeared in the October, 1974, issue of *73* written by Earl Dunn W5LCT. His squelch used 567 decoders to detect four sequential tones. I wanted to build a squelch for the two tones of my local fire department. So, out came the protoboard and my well-stocked junk box.

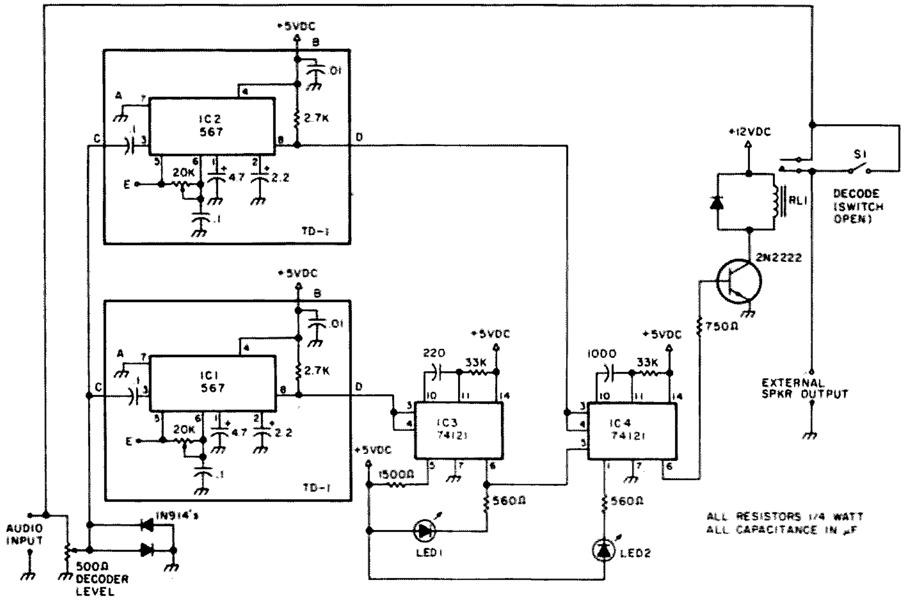

Fig. 1. Schematic.

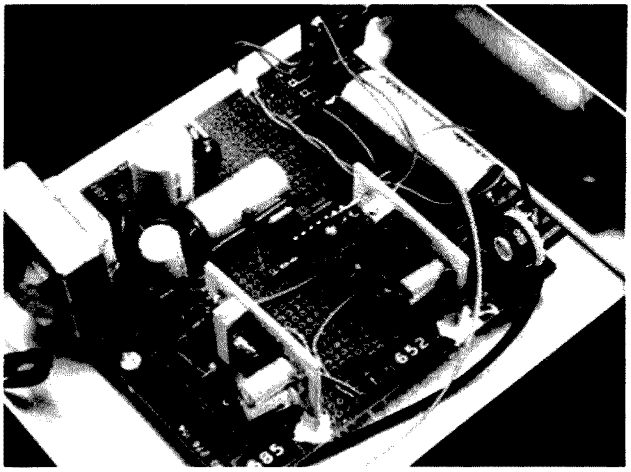
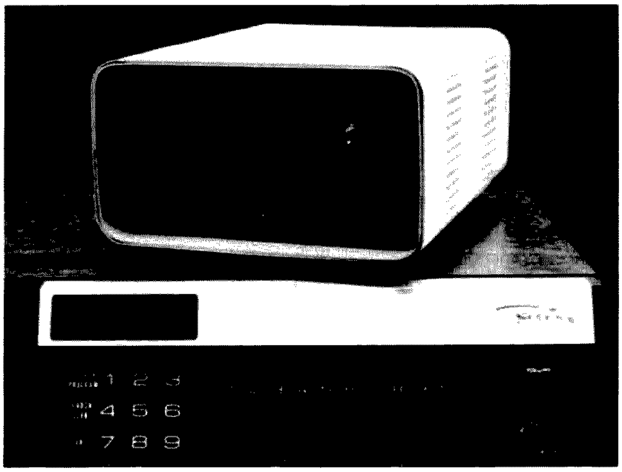
Redesigning the Squelch

Since I was interested in decoding only two tones, I set out to simplify W5LCT's circuit. I used Ramsey Electronics TD-1 tone-decoder kits for each tone. Their PC boards are easy to assemble, reliable, and cheap. Check the ads in the back of any *73*—I believe Ramsey has advertised in every *73* since they opened their doors for business. (Kind of reminds me of the antenna company "In *QST* since '53 without missing an issue." OK, old-timer—name that company.) Back to decoder kits.

The Ramsey TD-1 kit sells for $5.95 and comes complete with an on-board 5-volt zener. Since I needed 5 volts for the control logic and the TD-1 decoders, I built a regulated supply using a 7805 and eliminated the zener diode and series resistor, D1 and R3, that came with the Ramsey kits. The TD-1 boards are mount-



Inside view of the tone squelch. The TD-1 decoder kits are mounted vertically.



Overall view of the completed tone squelch. The squelch fits easily on top of the scanner.

ed vertically on the main board. The photo of my tone squelch shows the TD-1 boards next to the labels marking the decoder frequencies. The control logic, relay, and power supply are on the board behind the decoders. I used the copper pads on the board (Radio Shack 276-156) to wire the control and power-supply circuits.

Logic and LEDS

For my squelch to open, a 585-Hz tone must first be received, followed by a 652-Hz tone. Looking at the schematic, IC1 is tuned to 585 Hz. When that tone is received, the output of the decoder goes low. IC3 starts timing a six-second window and LED1 goes off. During this six-second period, a 652-Hz tone must be received and decoded by IC2. LED2 lights when the second tone is decoded. LED2 stays lit for about 25 seconds. During this time (set by the 1000-uF cap between pins 10 and 11 of IC4), the 2N2222 is turned on and relay RL1 pulls in, connecting an external speaker to the output of my scanner.

Building and Operating the Squelch

Building the tone squelch isn't all that difficult and layout isn't critical. The letters A through E marked on the schematic refer to points on the Ramsey TD-1 decoder boards. Relay RL1 came from my junk box. It's marked 360 Ohms at 12 volts and is a good starting point for substitution. I built a simple power supply using a 12-volt clock-kit transformer. A 1-Amp bridge rectifier followed by a 7805 regulator provides the 12 volts and 5 volts shown on the schematic. Both sides of the ac line are protected with an Elmenco fused plug.

The decoders are adjusted with the tone squelch's input disconnected from the scanner. A frequency counter is attached to point E on the decoder board. The 20k pot is adjusted until the counter reads the frequency you want to decode. Remember, IC1 must be set for the first tone and IC2 set for the second tone in the 2-tone sequence.

To operate the squelch, I plugged the audio input of the tone squelch into the external output of my scanner through a mating plug. An 8-Ohm speaker was connected to the output of the tone decoder. I used the idle tone from a local 152-MHz mobile-telephone channel to set the decoder levels. With the tone present, I set the decoder level pot for about 100 millivolts measured with an ac voltmeter at point C on the decoder boards.

Keep the decoder audio input as low as possible to narrow the bandwidth of the decoders. Also, with sequential tones as closely spaced as those in my squelch, the center frequency of each decoder can be slightly offset in opposite directions if decoder-falsing is a problem. In all cases use the minimum amount of audio at point C that permits reliable decoder operation.

After the decoders are set to frequency and the input level is adjusted, place switch S1 in the open or decode position. Audio from your scanner will be heard only after the correct tones are decoded in the right sequence. The 25 seconds of audio from your scanner can be adjusted by changing the value of the 1000-uF capacitor between pins 10 and 11 of IC4.

With the help of this squelch you, too, might end the battle with your television and hear those tone-encoded calls. ■

Parts List

2 Tone decoders, Ramsey Electronics, TD-1	$11.90
3 Diodes, 1N914 (276-1122)	.33
1 Transistor, 2N2222 (276-2009)	.79
2 LEDs (276-026)	.79
1 Potentiometer, 500 Ohms (271-226)	.59
2 Resistors, 560 Ohms	.19
1 Resistor, 750 Ohms	.10
1 Resistor, 1500 Ohms	.10
2 Resistors, 33k	.19
1 Capacitor, 220 uF (272-956)	.79
1 Capacitor, 1000 uF (272-958)	.79
1 Relay, RL1 (273-213)	4.49
	$21.05

Optional Power Supply

1 Transformer, 12 volts, 1.2 Amps (273-1505)	$3.99
1 Diode bridge, 1.4 Amps at 50 piv (276-115)	1.09
1 Voltage regulator, 7805 (276-1770)	1.59
1 Capacitor, 1000 uF, 35 WV dc (272-1019)	1.59
2 Capacitors, .22 uF, 50 WV dc (272-1070)	1.78
	$10.04

All numbers are from the 1982 Radio Shack Catalog No. 354.

Electronic Mail Comes of Age

These mailboxes may be thousands of miles away, but they're instantly accessible.

Has your mailbox had a little dust in the bottom of it recently? Have your friends forgotten how to write? Are you tired of all of the junk mail you've been receiving? Well, maybe it's just because you haven't been checking the *right* mailbox!

This article is designed to acquaint you with the new Message Storage Operation, more affectionately known as the MSO or Electronic Mailbox, and to give you some hints on proper ways to exploit the systems, where to find them, and a bit about on-frequency ethics. I hope to present the most important facts about the MSO, but since it is a wide-ranging subject, I'm sure that I will miss something and take this opportunity to invite you not only to experiment with the various MSOs to answer your questions, but also to correspond with me at the above address should you feel it necessary.

The Message Storage Operation is an adjunct to the ever-popular Hal DS-3100 Automatic Send-Receive Terminal, manufactured by the Hal Communications Corporation, Urbana, Illinois. For those of you who presently own a DS-3100 without the MSO, it can be added to your unit with a minimum of trouble and expense. The MSO is a completely solid-state device which adds mass storage to the DS-3100 and which can be accessed either locally or by remote users. It has a 32,768-byte capacity (approximately 450 lines of message storage or retrieval), which has shown to be more than adequate storage.

Control of the MSO can be accomplished by the local or remote user simply by typing a series of commands recognizable by the MSO. Files (messages) can be written to, read from, or deleted from the system by use of these commands, and a "Help" command is provided to assist in using the system. At this point, I would like to mention that the system is fully automatic, written with "fail-safe" features in mind, and cannot be harmed in any way by either the local or remote user. Everyone is a novice when he first uses any sophisticated system; the MSO is not only forgiving, but also will tell you quickly if you make any mistakes.

First and foremost concerning the use of the MSOs is a basic understanding of our frequency usage. No frequency is reserved, set aside, allocated, or otherwise designated for *only* MSO usage! It is important to observe some very basic rules and precautions *before* you activate one of the MSOs in order to prevent QRM to other users of the frequency, whether they be other MSO users or an already-established QSO on or near the frequency. Just as with any other frequency or mode you use, please *listen* on the frequency before you activate one of the systems. Propagation conditions vary from hour to hour, and it is important to listen for a few minutes on the frequency to keep from stepping on someone else who may be in QSO or using one of the MSOs. Your cooperation in this one area alone will do more for smooth operation of the MSOs than all of the other areas combined!

Just where do you find these mysterious electronic MSOs? Both 20 and 40 meters have well-established MSO operations. The frequencies of 14,085,625 Hertz and 7,096,375 Hertz are popular with many stations, and other smaller operations are appearing daily. I'm told that there is at least one MSO operating on 80 meters (in the western part of the United States), although I'm unaware of its frequency. Those who maintain MSO systems on the various bands almost without exception use some form of crystal control for their transmitters/receivers. Consequently, you can count on these MSOs appearing at the same spot on your dial in day-to-day operations.

This brings up our next most important subject relative to good frequency usage. It is very important that the tones emanating from your equipment match as closely as possible the tones output from the MSO. In this regard, tradition states that it is the mark frequency with which we measure RTTY frequencies. For instance, in order to successfully activate and use the MSO systems maintained on 20 meters, your mark tone (which is 2125 Hertz lower than your operating or carrier frequency) must land on 14,085,625 Hertz. Your digital readout may read 14,087.7 or some other reading, but it is the mark tone frequency that is important to match with the MSO. Off-frequency operation causes many difficulties, some of which are: unsuccessful activation and de-activation of the MSO, QRM from "fishing expeditions" trying to find the frequency, unsuccessful .WRITE, .READ, and .DELETE commands, and a general lack of smooth operation of the MSO. Modern demodulators have *sharp* front-end filters and, as such, require a very close match to successfully demodulate RTTY signals!

Now that we are sure that the frequency is clear and that we have our transmitting/receiving equipment on the correct frequency, let's talk a bit about some "golden rules" for MSO usage:

1) Anonymity is great, but the FCC *requires* that you properly identify your station! So, please properly identify your station when you are utilizing the MSOs.

2) Always start your transmissions to the MSOs with a short "mark hold" of 2 to 3 seconds, followed by at least one carriage return/line feed (CR/LF). This stabilizes both your equipment and that of the MSO.

3) Each command to the MSO must be preceded by a period, (.WRITE, .READ, .DELETE, etc.) and the command must be "left justified" (positioned on the extreme left margin). Commands sent to the MSO from other than the left margin or without the period are ignored. The only exceptions to this are the Access Code and the four Ns (NNNN), which may be sent from any position in the print line.

4) Limit your messages to that information necessary to get the message across. In *all* cases, limit your message to *less than* ten minutes in length, in order to comply with FCC identification requirements.

5) Please utilize the .DELETE command to remove messages directed to you from the MSO after you have .READ them.

6) Please use the .SDIR (short-form directory) in lieu of the .DIR (long-form directory) unless you need the information in the long-form directory.

7) Be *sure* to use the .EXIT command to deactivate the MSO when you are through. Failure to shut down one MSO means that it may respond to commands directed to another MSO on the frequency. This does cause a bit of confusion!

As stated earlier, the MSO system does contain a .HELP command to refresh your memory on the various commands available and a .FILEHELP command to help in constructing files and passwords. Please note that there is a mandatory space character between the .WRITE command and the file name and mandatory carriage return/line feed immediately after the file name. (A carriage return/line feed after each command to the MSO is highly recommended!)

The file name can be any combination of letters and numbers that the receiving station will recognize. Typically, the file name is something like this: .WRITE KØVKH DE K4KOZ (CR/LF). This immediately tells KØVKH that he has a message waiting for him in the MSO and that it is from K4KOZ. The MSO will not accept duplicate file names, so if it is necessary to .WRITE a second message to the same station (while the first one is still on file in the MSO), then make the second file name distinctive by adding a number or letter, e.g., .WRITE KØVKH2 DE K4KOZ (CR/LF).

Since file names are very distinctive, it is additionally important to send the exact information to the MSO when using the .READ or .DELETE commands, even if it is misspelled in the directory. Without the correct file name, the system will return the "file not found" statement.

In conclusion, the MSOs are providing a very satisfactory service on RTTY, CW, and ASCII, both on the HF and the VHF bands. MSO owners derive a lot of personal pleasure in providing these mailbox services and, speaking for myself, I encourage all those who have need for this service to use my MSO at their leisure. I maintain it on 14,085,625 Hertz during the daylight hours and my access code is MSOVKH (no spaces between letters). Hope to see you on RTTY soon! ■

ALL BAND TRAP ANTENNAS!

PRETUNED - COMPLETELY ASSEMBLED - ONLY ONE NEAT SMALL ANTENNA FOR UP TO 7 BANDS! EXCELLENT FOR CONGESTED HOUSING AREAS - APARTMENTS LIGHT - STRONG - ALMOST INVISIBLE!

FOR ALL MAKES & MODELS OF AMATEUR TRANSCEIVERS - TRANSMITTERS - GUARANTEED FOR 2000 WATTS SSB 1000 WATTS CW. INPUT FOR NOVICE AND ALL CLASS AMATEURS! IMPROVED DESIGN!

COMPLETE AS SHOWN with 90 ft. RG58U-52 ohm feedline, and PL259 connector, insulators, 30 ft. 300 lb. test dacron end supports, center connector with built in lightning arrester and static discharge - molded, sealed, weatherproof, resonant traps 1"X6"- you just switch to band desired for excellent worldwide operation - transmitting and receiving! Low SWR over all bands - Tuners usually NOT NEEDED! Can be used as inverted V's - slopers - in attics, on building tops or narrow lots. The ONLY ANTENNA YOU WILL EVER NEED FOR ALL DESIRED BANDS - WITH ANY TRANSCEIVER - NEW - EXCLUSIVE! NO BALUNS NEEDED!

60-40-20-15-10-6 meter - 2 trap --- 104 ft. with 90 ft. RG58U - connector - Model 998BUC ... $99.95
40-20-15-10 meter --- 2 trap --- 54 ft. with 90 ft. RG58U - connector - Model 1001BUC $98.95
20-15-10 meter --- 2 trap --- 26ft. with 90 ft. RG58U - connector - Model 1007BUC $97.95

Octal Ingenuity

It's an old radio. You can't find a replacement tube. Now what do you do?

One day my mother-in-law handed me an old Philco "antique radio" and said, "Franklin, you're a ham. How about fixing my radio?" I took one look at that old ac/dc battery thing and was about to say I was too busy, but then those words, "you're a ham," shook me up. If I didn't fix it, ham radio would be defamed and I would be one degraded Extra-class amateur. If I did fix it, both ham radio and I would still be highly esteemed, at least in her mind.

"Sure, I'll give it a try," I said. And the fun began.

Now this old thing was typical for its day. (See the block diagram in Fig. 1.) There were no doubt millions of these sets built, and this particular one looked well-built, mechanically. Electrically, too, it must have been pretty good to survive this long.

After plugging it in and getting not a peep out of it, I decided to use the usual plan of attack for these jobs. Check the tubes first.

This had to be done without the help of a tube tester. Time to think. If the set is completely dead, a tube fault causing this would probably be catastrophic. Most common in this category is an open filament; then come short circuits and open elements.

It's a good thing I kept that old beat-up RCA tube manual. A check for which pins to test with the ohmmeter didn't take long, and neither did finding the problem. The 3Q5 audio power amplifier filament was open. What luck! I'll just walk right down to my nearby radio store and get a new one.

What, no 3Q5?! And still no 3Q5 three days later, with a telephone bill to raise my wife's ire. Say, this thing *is* an antique radio. Oh, I found a place where I

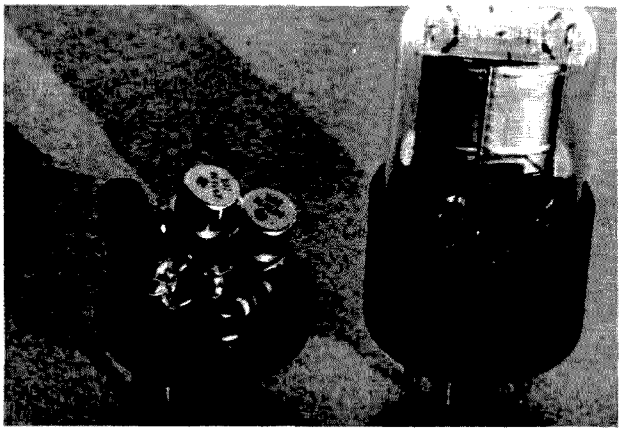

Photo A.

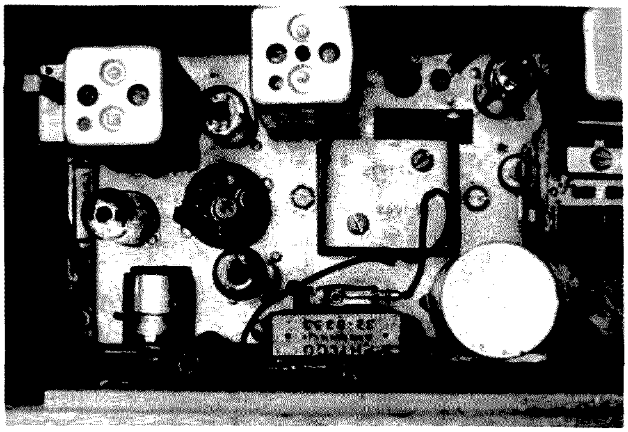

Photo B.

could get a 3Q5 for $4.00, but minimum orders were for $25.00.

Why sweat the small stuff? I'll simply transistorize the stage.

Now here begins my story for fellow hams. Not being of the mathematical type, but having a good supply of parts and test equipment, I'll use the tried and proven practical approach.

First, we'll want to know as much as needed about the tube to be replaced. The RCA tube manual gives the essentials: filament 2.8 V at 0.05 A, maximum plate current 8.5 mA, maximum power output 330 mW at 8.5% THD. Obviously, we are not working with high power or high fidelity, so the replacement job looks easy so far.

Next, we'll need to determine what circuit characteristics must be known. Remember, this is an ac/dc battery-type radio. This type had some strange circuitry which was not well standardized. No schematic is available, so an hour or so must be spent in tracing out what is required of the circuit.

The power supply circuit as traced out is shown in Fig. 2. Notice how the filaments of all but the 117Z3 rectifier are supplied from the B+ through suitable dropping resistors R1 and R2. The 3Q5 cathode resistor (680 Ohms) must be viewed as both shunted by the series string of filaments and as affecting the division of B+ current supplied to the filaments. Notice the 30-uF capacitor at pin 7 of the 3Q5 to common. If this is shorted, it could be the cause of open filaments in the 3Q5. Now is the time to check this. (It was OK in this set.)

Further circuit checks show this amplifier as a straightforward pentode power-amplifier stage (see Fig. 3). The main features to note here are associated with the power supply of Fig. 2. The grid resistor is returned to common through the 1R5 filament. This places the grid 1.4 V dc above common. The 3Q5 filaments are above common by four 1.4-V filaments. This places the 3Q5 cathode potential at about 7 V dc above common. Grid bias was about $1.4-7=-5.6$ V.

Now we should decide on what type of transistor amplifier circuit to use. Here is where past experience and a general knowledge of transistor amplifier circuits comes in handy. For this case we'll use Darlington-connected, high-voltage transistors such as the 2N5058 (Radio Shack RS-2008); see Fig. 4. This circuit provides a high input impedance as needed for the first af amplifier stage and more than enough gain and power output capability. The choice of transistors meets or exceeds the voltage and power needs.

Resistor R1 is the base bias resistor. It will be determined by experimentation and added as part of the transistor amplifier plug-in module. Resistor R2 is the base bias divider resistor, which may be the 2.2-meg resistor already in the radio. Resistor R3 is added to control the division of current

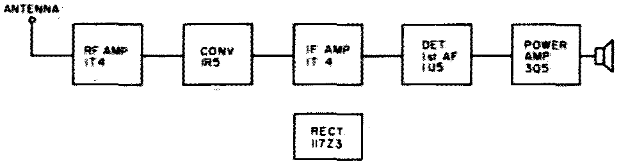

Fig. 1. Block diagram.

between Q1 and Q2. Resistor R4 is the emitter swamping resistor used for temperature stability. It is shown entirely bypassed by C2, but we will experiment with the circuit to determine how much we need or want bypassed. Capacitors C1 and C3 as well as the output transformer are already in the radio. These are used as is.

Let's begin the design and construction. First, use *CAUTION*. Use an isolation transformer as you always should when working on ac/dc equipment not having its own transformer.

Make up an octal plug with wires out to a breadboard setup. This can be done nicely in this case because we are working with low frequencies and relatively low gain. The octal plug is inserted into the 3Q5 socket and the breadboard set up near by.

Initially, calculate or determine component values by Ohm's Law and past experience examples. The resistor replacement for the 3Q5 filament, for example, is determined by Ohm's Law as $R=E/I=2.8/0.05=56$ Ohms. Power is $P=EI=2.8\times0.05=0.14$ Watts. So use some value near 56 Ohms having a power of at least ¼ Watt to start with.

Resistor R3 in Fig. 4 is calculated to guarantee at least 250 uA in Q1 by assuming that this amount of current will be through it when the Q2 normal V_{BE} of 0.65 V is present. $R=E/I=0.65/250\text{ uA}=2.7\text{k}$. Power in this resistor is insignificantly low.

Install the 56-Ohm and 2.7k-Ohm resistors on the breadboard. Use resistor substitution boxes or junkbox resistors for R1 and R4. Initially, set R1 for its highest value (10 meg). Set R4 at 1k Ohms initially. Capacitor C2 may have a starting value of 10 uF at 10 V or more. Try all of the three possible near common pins (2, 8, and 7) of the 3Q5 socket one at a time for the circuit common.

Check radio operation for output at about 1/3 volume-control setting. Also check and record filament voltage at pin 7 relative to common, dc current through R4 (via voltage drop and Ohm's Law), and

feel the transistors for heat. *Caution:* Remove voltage just prior to touching the transistors, as up to 100 volts may be present. Change values of components in small steps until you obtain correct filament voltage (5.6 V), less than maximum current (8.5 mA), sufficient output volume with low distortion, and operation with neither transistor more than slightly warm to the touch.

My final circuit was easily constructed on an octal plug (see Photo A) and provided what seemed to Mother more volume and clearer tones than she had ever heard from this set.

The final circuit is shown in Fig. 5. The original 680-Ohm resistor was disconnected inside the set so that pin 8 could be used as a tie point on the plug. The final filament resistor value was 150 Ohms (not the calculated value of 56 Ohms). This also was wired inside the set although it could have been placed on the octal plug. Final amplifier current was a surprisingly low 2 mA. Both transistors were at only body temperature or less.

Notice that the 2.2k-Ohm resistor is bypassed with a 0.5-uF capacitor, but connection to pin 2 for the common return effectively places the 150-Ohm filament resistor in the circuit unbypassed. This helped to raise input impedance as well as to lower distortion. The increased input impedance must have offset gain reduction in this stage because gain was still more than enough.

The 220-pF capacitor was added to eliminate high-frequency hiss. The source of this may have been a poorly filtered signal from the detector or a parasitic oscillation in the transistor stage.

For the last two years now, my mother-in-law hasn't had one bad thing to say about ham radio. She seems well satisfied as she sits in her rocking chair listening to those far-away stations. ■

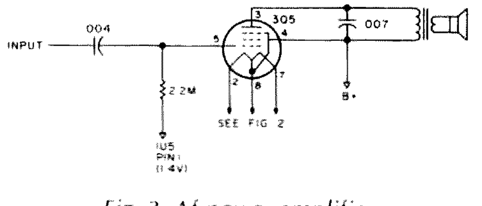

Fig. 3. Af power amplifier.

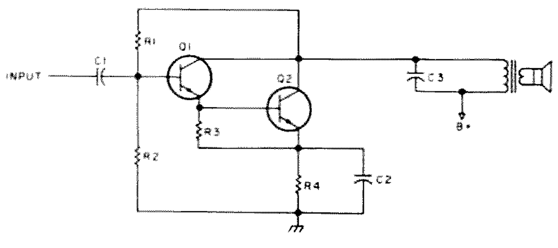

Fig. 4. Transistorized af power amplifier.

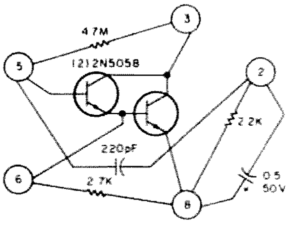

Fig. 5. Final circuit. (Top view of octal plug.)

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

SOUTH GREENSBURG PA
NOV 5

The Foothills ARC will hold its fifteenth annual hamfest on Saturday, November 5, 1983, at St. Bruno's Church, South Greensburg PA. Tickets are $2.00 or 3 for $5.00; indoor flea-market tables are $5.00. Refreshments and food will be available. Talk-in on 146.07/.67. For further information, advance tickets, or tables, contact WA3HOL, or write FARC, PO Box 236, Greensburg PA 15601.

STONE MOUNTAIN GA
NOV 5-6

The Alford Memorial Radio Club, Inc., will host its 11th annual Hamvention on November 5-6, 1983, at Stone Mountain Park, Stone Mountain GA. Hours on Saturday are 9:00 am to 5:00 pm and on Sunday, 9:00 am to 3:00 pm. The admission fee of $3.00 includes a Saturday night cookout for the entire family and variety entertainment. There will be FCC exams, seminars, dealers, a gigantic flea market, and free parking. Camping will be available in the park. Talk-in on 146.16/146.76. For further details, send an SASE to Lew Howard W4LHH, 4132 Creek Stone Court, Stone Mountain GA 30083, or phone (404)-292-5469.

TAYLOR MI
NOV 6

The RADAR seventh annual hamfest, flea market, and swap will be held on Sunday, November 6, 1983, from 8:00 am to 3:00 pm, at Kennedy High School, Kennedy Drive, corner of Northline, Taylor MI. Admission is $2.00. Tables are $1.00 per foot (8-foot tables) and reserved tables must be paid for in advance. Dealers may set up at 7:00 pm on Saturday and 6:00 am on Sunday. Send check or money order to RADAR, Inc., PO Box 386, Taylor MI 48180. Talk-in on 147.93/.33 and 146.52. For more information, phone Bea Johnson at (313)-561-3911.

WEST MONROE LA
NOV 12

The Twin City Ham Club will hold a hamfest on Saturday, November 12, 1983, from 8:00 am through 5:00 pm, at the West Monroe Convention Center, West Monroe LA. There will be a variety of dealers as well as plenty of space for swap tables. Talk-in on .25/.85 and .52/.52. For further information, contact Benson Scott AE5V, 107 Contempo, West Monroe LA 71291.

MT. PROSPECT IL
NOV 13

The Mt. Prospect Amateur Radio Club and Tri-County Emergency will sponsor RA-COM '83 on November 13, 1983, beginning at 8:00 am, at Prospect High School, 801 W. Kensington, Mt. Prospect IL. Features will include a large indoor electronics flea-market area, commercial exhibits, and seminars. Talk-in on 146.52. For more information and flea-market or commercial booth reservation forms, send an SASE to RA-COM, PO Box 452, Mt. Prospect IL 60056.

NORTH HAVEN CT
NOV 13

The Southcentral Connecticut Amateur Radio Association (SCARA) will hold its 4th annual electronics show and flea market on Sunday, November 13, 1983, from 9:00 am to 3:00 pm, at the North Haven Recreation Center, Linsley Street, North Haven CT. Admission for all events all day is $1.50; children under 12 accompanied by an adult will be admitted free; tables are $7.00 in advance and $10.00 at the door. Features will include the latest in ham radio, computer, and domestic electronics and software. There will be free technical seminars, ARRL information and programs, a bake sale, and a Christmas/Chanukah gift bazaar featuring non-electronic gifts. Tables for the gift bazaar will be available only in advance. Doors open for vendors at 8:00 am. Food will be available all day. For reservations, send a check, payable to SCARA, to Ed Goldberg WA1ZZO, 433 Ellsworth Avenue, New Haven CT 06511, and include an SASE for confirmation and directions. For further information, phone (203)-773-0646 (home) or (203)-852-7876 (work).

FORT WAYNE IN
NOV 13

The Allen County Amateur Radio Technical Society (AC-ARTS) will hold its 11th Fort Wayne Hamfest on November 13, 1983, at the Allen County Memorial Coliseum, Fort Wayne IN. Tickets are $2.50 in advance and $3.00 at the door; children under 12 will be admitted free. Regular tables are $6.00, premium tables are $20.00, and parking is $1.00. There will be forums on OSCAR, fast- and slow-scan TV, 10m FM, audio, computers, and traffic handling. Talk-in on .88 and .52. For advance tickets (include an SASE with your request and send before the November 1st deadline) and more information, write to Hamfest Chairman, AC-ARTS, Inc., PO Box 10342, Fort Wayne IN 46851.

SELLERSVILLE PA
NOV 13

The R. F. Hill Amateur Radio Club will hold its annual Winterfest Amateur Radio Flea Market and Exhibit on Sunday, November 13, 1983, at the Sellersville National Guard Armory, PA route 152, Sellersville PA. Take Sellersville or Perkasie exits from PA route 309. The location is approximately halfway between Philadelphia and Allentown. Admission for buyers is $2.00. Rates for sellers for indoor space is $4.00 and for outside tailgating space, $3.00. Refreshments will be available on site and there are many good places to eat nearby. Flying hams should land at Pennridge Airport in Perkasie PA. Talk-in on 144.71/145.31 (Almont PA), 146.28/146.88 (Souderton PA), and 146.52 simplex (local area). For additional information, write PO Box 29, Colmar PA.

MASSILLON OH
NOV 13

The Massillon Amateur Radio Club will present the ARRL-approved Auction Fest '83 on Sunday, November 13, 1983, at the Massillon Knights of Columbus Hall, 988 Cherry Road NW, Massillon OH. Tickets are $2.50 in advance and $3.00 at the door, and children under 12 will be admitted free. Each 8-foot table is $5.00. The flea market will begin at 7:00 am, doors will open at 8:00 am, and the auction will begin at 11:00 am. Food will be available and the hall is easily accessible for the handicapped. Talk-in on 147.78/.18. For advance reservations and tickets, send an SASE to Massillon ARC, 920 Tremont Avenue SW, Massillon OH 44646.

ALPINE NJ
NOV 19

The Stateline Amateur Radio Club of New York and New Jersey will hold Radiosport '83 on Saturday, November 19, 1983, at the Alpine Boy Scout Campgrounds, Alpine NJ (just off exit 2 of the Palisades Interstate Parkway). Children under 12 will be admitted free. The demonstrations, technical discussions, and dealer and commercial displays will be in a large, indoor, well-lit, heated facility with ample parking, including spaces for tailgating (weather permitting). A refreshment stand will be available, as well as an engineering table with special test equipment available for checking deviation, output, swr, etc. Talk-in on 146.235/.835 and 146.52. For further information and/or table or booth reservations, contact Abel David, Jr. KX2F, 82 Lexington Avenue, Dumont NJ 07628, or phone (201)-387-8129.

BILLERICA MA
NOV 19

The Honeywell 1200 Radio Club and the Waltham Amateur Radio Association will hold their annual amateur radio and electronics auction on Saturday, November 19, 1983, beginning at 10:00 am, at the Honeywell Plant, 300 Concord Road, Billerica MA (exit 27 off route 3). There will be a snack bar, a bargain parts store, and free admission and parking. Talk-in on 147.72/.12 and 146.04/.64 (club-sponsored repeaters). For more information, contact Doug Purdy N1BUB, 3 Visco Road, Burlington MA 01803.

VERO BEACH FL
NOV 19

The Treasure Coast Hamfest will be held on November 19, 1983, at the Vero Beach Community Center. Admission is $2.50 in advance and $3.00 at the door. Features will include tailgating and a QCWA luncheon. Talk-in on 146.13/.73, 146.04/.64, and 222.34/.94. For more information, write PO Box 3088, Beach Station, Vero Beach FL 32960.

CLEARWATER FL
NOV 26-27

The Florida Gulf Coast Amateur Radio Council will sponsor the Florida State ARRL Suncoast Convention on November 26-27, 1983, from 9:00 am to 4:00 pm both days, at the Sheraton Sand Key Resort, Clearwater FL. Registration is $3.00 in advance (until November 18th) and $4.00 at the door. Saturday will feature a QCWA luncheon ($7.00 per ticket), the ARRL forum hosted by Frank Butler W4RH, and a luau in the evening ($15.00 per ticket). Sunday will feature a ladies' luncheon ($7.00 per ticket). Activities will include a flea market ($12.00 for both days for swap tables), technical talks, and demonstrations. Talk-in on .37/.97, .96/.36, and in Tampa, .16/.76. For hotel room reservations, write Sheraton Sand Key Resort, 1160 Gulf Boulevard, Clearwater FL 33515, or call (813)-595-1611 (mention the Sun-

GREENSBORO NC
NOV 26-27

The Guilford Amateur Radio Club will hold its annual Hamfest/Computerfest on November 26-27, 1983, beginning at 9:00 am each day, at the National Guard Armory, Greensboro NC. Pre-registration is $3.50 and registration at the gate is $5.00. Tailgating is allowed with the price of admission. An equipment check-out booth with test equipment and a technician will be available as a free service for those wishing to check used equipment prior to purchase. Food and free parking will also be available. Talk-in on 144.65/145.25 and 146.52 simplex. For more information and advance tickets (checks to be made payable to GARC), send an SASE to GARC, PO Box 7007, Greensboro NC 27407.

OAK PARK MI
NOV 27

The Oak Park High School Electronics Club will hold its 14th annual Swap-n-Shop on Sunday, November 27, 1983, from 8:00 am to 4:00 pm, at the Oak Park High School, Oak Park MI. The east and west doors will open at 6:00 am. Admission is $2.00 and 8-foot tables are $6.00. Refreshments will be available. For more information, send an SASE to Herman Gardner, Oak Park High School, 13701 Oak Park Boulevard, Oak Park MI 48237, or phone (313)-968-2675.

STONY BROOK LI NY
NOV 27

The Radio Central ARC will sponsor its 5th annual Ham-Central, 1983 edition. This ARRL hamfest will be held on Sunday, November 27, 1983, from 9:00 am to 3:00 pm, in the social hall of Temple Isaiah, 1404 Stony Brook Road, Stony Brook LI NY. General admission is $3.00; children under 12 and XYLs will be admitted free. An 8-foot table space is $7.00 and includes one free admission. Doors will open at 7:30 am for dealers and sellers (ham-related items only). There will be food, drinks, and free parking available. Seminars will feature speakers Art Greenburg W2LH and Madeline Greenburg W2EEO on antennas and Harry Dannals W2HD on the future of ham radio. Talk-in on 144.550/145.150 and 146.52. For reservations and additional information, contact Scotty Policastro KA2EQW, 80 7th Street, Bohemia NY 11716, (516)-589-2557, or Bob Yarmus K2RGZ, 3 Haven Court, Lake Grove NY 11755, (516)-981-2709.

FARIBAULT MN
DEC 3

The annual Handi-Ham Winter Hamfest will be held on Saturday, December 3, 1983, at the Eagles Club in Faribault MN. Registration will begin at 9:00 am. There will be a Handi-Ham equipment auction and a dinner at noon. Talk-in on .19/.79. For more information, contact Don Franz W0FIT, 1114 Frank Avenue, Albert Lea MN 56007.

HAM HELP

I need the schematic for a Digi Scan 8 by Unimetrics. This is an 8-channel scanner.

Dan Quinn KA4CJE
Rt. 3, Box 818
Palatka FL 32077

Does anyone have a spare range selector switch for the Heath MM-1 VOM? It is no longer available from Heath.

Charles Guthy
24 Pinewood Ave.
Sudbury MA 01776

Wanted: maintenance manuals for the Aida 103 and 103A HF transceivers. I want to convert the 103 to include 15 meters.

Fr. Joseph Vaughan KC2LJ
Frontier Rd.
Churubusco NY 12923

I need manuals and schematics for the following equipment: the Eico model 323 VTVM and model 324 signal generator; the Heath model IM-18 VTVM; and the DuMont 401-A oscilloscope. I also need a spare power transformer for the DuMont 401-A. I am willing to purchase originals, copy and return the original, or reimburse your copying and mailing costs.

H. W. Hall WB4OGM
492 Selfridge Drive
Colorado Springs CO 80916

I have been searching for the service manual, schematic, and parts list for the Telequipment S-54A oscilloscope. I will gladly pay copying costs.

Raymond L. Wood WB4MOM
Rt. 5, Box 93
Elizabeth City NC 27909

I need modification information for the Yaesu FT-2 (B or F version). I am especially interested in frequency-synthesis modifications.

Richard Metro KA2QWH
201-D Springmeadow Drive
Holbrook NY 11741

I need a copy of the manual for the Heath model QF-1 Q-multiplier.

Robert Schlaget N7BH
2302 288th St. East
Roy WA 98580

I need the schematic and operating manual for the Heath HX-11 CW transmitter. I will pay for copying and mailing costs.

Carl Walczewski KB1EH
141 Booth St.
New Britain CT 06053

I need help in locating the wiring diagrams for the Hewlett-Packard model 150 oscilloscope and model 152-B dual-trace amplifier.

SATELLITES

INITIAL ORBITAL TIMES FOR STS-9

Any given orbit begins as the spacecraft crosses the equator traveling west to east. The following orbital operating times are based on an 11:30 AM EDT launch on October 28th. If the launch is delayed for any reason, you must add the amount of the delay to the times stated here to obtain new orbital track timing for an operating pass. Also, what we are listing here are only the "official operating periods" scheduled as of September 3rd. Dr. Garriott says he will attempt to provide other "unofficial" operating periods as well, but these will have little advance notification. Whenever possible, advance notice of these extra operating times will be made available over W1AW, in bulletins issued by NASA-affiliated radio clubs (such as W5RRR in Houston), and on the daily updates of the Westlink Radio Network Hollywood newsline: (213)-465-5550. All North American passes are listed in local time, while those for foreign contacts with the spacecraft are in UTC. All times are approximate for the start of a given pass. You may calculate the specific time over your QTH by adding the forward speed of the space vehicle, which is 17,000 miles per hour.—*Thanks to Roy Neal K6DUE and the* Westlink Report.

Orbit #	Date	Ground Track	AOS Time
39	10/30	Spokane, Denver, Dallas, Houston, New Orleans, S. America	2000 CDT
40	10/30	N. California, down Pacific coast E. of San Francisco and LA, Mexico	1930 PDT
47	10/31	W. Australia, S. America, Europe	1430 UTC
		NOTE: Standard Time begins this date	
63	11/1	S. America, USSR, India, Australia	1330 UTC
64	11/1	Iran, Scandinavia, USSR	1555 UTC

79	11/2	N. tip of S. America, Caribbean, N. Europe, USSR, India	1250 UTC
80	11/2	Caribbean, all E. Coast states, Newfoundland, UK, central Europe	0815 EST

AMSAT SYMPOSIUM

AMSAT will hold an Amateur Radio Satellite Symposium in conjunction with its annual meeting on Saturday, November 12, 1983, at the Johns Hopkins University Applied Physics Laboratory just off I-95, between Baltimore and Washington. The planned programs include: how to get on the new OSCAR 10 satellite, tracking OSCAR 10 with/without a computer, a report on the W5LFL Space Shuttle operation, PACSAT, and, much, much more! Admission is free but advanced reservations are required. For further information and reservations, contact AMSAT, PO Box 27, Washington DC 20044, or call (301)-589-6062.

PACKET RADIO

ASCII—USA/AX.25
HDLC CONVERTER

USA/AX.25 is the AMRAD approved digital format STANDARD used on amateur packet radio networks.

PAC/NET board only $80.00
Assembled/Tested. No ICs. 90 day warranty

Package of all ICs except 2-2716 EPROMs $80.00

PAC/NET SYSTEM

PAC/NET SYSTEM $240.00
System Tested 4.5 x 6" board complete with all ICs and programmed EPROMs personalized for each purchaser. Requires only single 8-10 volt ½ amp power. 1 year guarantee of hardware/software/AX.25 standard RS232 serial ASCII at any user baud rate. RS232 HDLC for 202 modem used for AFSK or direct to RF equipment for FSK.

DR. DIGITAL

Robert Swirsky AF2M
412 Arbuckle Avenue
Cedarhurst NY 11516

Practically every mode of communication used by an amateur-radio operator makes use of sound. Obviously, in voice communications, sound is directly processed by our brains. In CW communications, unless you are using a code reader or a flashing light, the radio signal is converted into a tone for us to hear. What is not so obvious is that sound is also crucial for "digital" communications. The only way to send a digital signal over communications equipment designed for voice is to convert it into tone signals. On the receiving end, special hardware is needed to convert the tone signals back into digital pulses.

All modern computers employ digital circuitry; they can only deal with signals that are either "high" or "low" (commonly represented with +5 V and 0 V in TTL-based computer systems). Since sound is of an analog nature, computers cannot deal with it directly. One way of dealing with sound is with circuitry adjusted to respond to certain frequencies. This method is useful if only a small number of sound frequencies needs to be detected. A common example of this is a RTTY decoder. Usually a pair of tuned circuits (or sometimes phase-locked loops) is used—one circuit is tuned to the "mark" frequency while the other is tuned to the "space." If, however, more than a few tones must be decoded, more sophisticated circuitry is needed. For applications such as speech digitizing (recording speech in digital computer memory), usually an analog-to-digital converter circuit is used. These are available as integrated circuits. Some of the more expensive A/D converter chips are quite fast; conversion time is just a few microseconds.

I am a software oriented person. I will go to extremes to solve a problem by using fancy software techniques rather than hardware. Perhaps it's because I am the world's worst solderer, or maybe because I am totally uncoordinated when it comes to handling small electronic components, that I have developed my distaste for electronic construction projects.

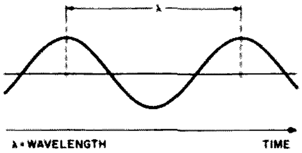

Fig. 1. How a wavelength is measured.

Because of my software vs. hardware attitude, I use software to deal with sound problems. Using some surprisingly simple algorithms, it is possible to analyze audio information with a microcomputer.

Before I go into software techniques for dealing with sound, let's review what the phenomenon of sound is all about. As you probably know, sound is carried by waves in some sort of a medium. When a reed, for instance, is set vibrating, it compresses the air immediately surrounding it. Due to the elastic nature of air molecules, the compressed air spreads out and compresses its neighboring molecules. It is this "bucket-brigade" effect that causes sound to travel. (Note that the molecules themselves aren't being compressed, it is the space between them.) In a denser medium, such as water, steel, or air at a higher pressure, sound will travel faster because the elasticity is greater. Conversely, less dense media will carry sound at a slower rate.

Sound frequencies that human beings can hear range from about 16 Hertz to about 25,000 Hertz, a *Hertz being* a cycle per second. Another way of measuring the frequency of a sound is by wavelength. Fig. 1 shows a diagram of a wavelength: a measure of the distance from one point on a wave to another corresponding point. The example I used shows it being measured from peak to peak. A wavelength can be expressed in terms of length in linear units (e.g., inches) or in time units (e.g., milliseconds). When working with a computer, it is convenient to measure wavelength in time units. After all, everything in a computer is clocked to a stable reference frequency.

Last month, we discussd a circuit known as a zero-cross detector. This simple circuit, consisting of an operational amplifier and a few additional components, makes it possible to do a number of things with sound waves. While you can only measure frequency information with such a circuit (any waveshape information is undetected), that is enough for many applications. Besides, the Apple II, II+, and *IIe* computers have the zero-cross detector built in; it is what the cassette interface uses. This means with an Apple or Apple-compatible computer, no additional interface hardware is needed to measure the frequency of a tone.

When writing software to process audio signals, it is necessary to use assembly language; high-level languages are just too slow to be useful. Also, with assembly language, it is possible to know exactly how much time an instruction takes to execute. This is critical when accurate timing loops are needed. Since the Apple II computer uses a 6502 microprocessor, the programs here will be written for that microprocessor. The algorithms, however, will be the same for any microprocessor.

Perhaps the simplest way to measure frequency is to have the computer count from one state change of the cassette port (zero cross detector) to another. Looking at Fig. 2, we see that the state changes every half-cycle. Using this information, an algorithm to measure frequency would be:

1. Wait for the port to become negative.
2. Increment a counter by 1.
3. Check the port.
4. If negative, go to step 2; if not, stop.

Now, to determine frequency from the result in the counter, some things need to be calculated. Take a look at Program 1. Notice the numbers in parentheses after some of the instructions; these are the execution times (i.e., the amount of time it takes for the computer to perform the instruction) measured in clock cycles. The Apple computer runs at a speed of 1,023,000 clock cycles per second. Once around the loop in the program takes 9 clock cycles. If, after exiting the loop, the counter has counted to 50, this means that 50 × 9 × 1/1023000 seconds have elapsed, or that one half-cycle takes 0.0004399 seconds. Since these are half-cycle, we multiply this by 2 to get 0.0008798 and take the reciprocal. This leaves us with 1138.66667 as the frequency in Hertz.

This method of counting a time interval between half-cycles is simple and quick, but not very accurate. The resolution (i.e., the closest frequencies that can be distinguished) is poor, and gets worse at higher frequencies. Some ways of improving this would be to raise the clock frequency of the computer, or count for a number of cycles. The problem with counting for a number of full cycles, as opposed to one half-cycle, is that the counting loop gets more complex and takes more clock cycles to execute. If the loop takes a longer amount of time to execute, frequency resolution is lost. Still, this is probably the best method when high speed is needed and close resolution is not. Certainly this method would be useful for decoding wide-shift RTTY, or even the tones needed for SSTV if you are only testing for a limited number of gray levels. The program in listing 1 has some limitations. Perhaps its greatest one is that it uses an 8-bit register to store the count. Because of this, low frequencies cause it to loop around to zero and start again. One possible solution, at the cost of 2 clock cycles per iteration, would be to add a BEQ OUT instruction after the INY. This way, if a result of zero is returned from the subroutine, you know to ignore it. Of course, one can make use of the counter "wraparound" to measure low frequencies.

The most accurate way of measuring frequencies on a microcomputer is to actually count the cycles for 1 second. The result would be directly in Hertz, and resolution would be to 1 Hertz. If a computer has an interrupt timer, it can be used to ensure that the count program runs for one second and then stops. Unfortunately, due to the way the Apple's sytem ROM is configured, it makes it very difficult to deal with interrupts.

The way around this problem is to have run through the program that counts cycles a fixed number of times. It is essential that the cycle-counting portion of the program take exactly the same amount of time to execute each time it runs. This is

Program listing 2.

trickier than it sounds; if a conditional branch takes place, the entire routine must execute in the same amount of time as it would if the branch did not occur. Also, to measure reasonably high frequencies, the counting loop must take as little time as possible.

Program 2 shows a frequency-counting subroutine that counts zero crossings on the Apple cassette port for a fixed amount of time. When used with Program 3, a Basic program to do some floating point calculations, it can measure frequencies with a resolution of 1 Hertz. If your Apple's clock is running at the proper frequency, it should give you fairly accurate results.

Lines 10 through 18 of Program 2 initialize various memory locations. The current status of the cassette port is examined and stored in memory location LAST. The X and Y index registers are set to zero, and the zero-page memory location ZP is set to 124. ZP controls the number of iterations that the LOOP, starting at line 31, is executed. As each iteration of LOOP takes 8192 clock cycles, the timing portion of the program will take 1,015,808 clock cycles—just a little bit under a second. (The difference is corrected in Program 3.) Now look at the LOOP portion of the program (line 31). I have indicated the number of clock cycles that each instruction takes in parentheses. (The 2/3 means that the instruction can take 2 or 3 cycles, depending on whether the branch is taken.) This routine will always take 32 clock cycles to execute, while it is performing the actual counting. The time spent before it starts to count is irrelevant. Notice that whenever the iteration counter goes through 256 iterations, it returns to MLOOP at line 20. MLOOP clears the registers, accumulates the zero-cross count, and calls the subroutine LOOP again. It does this 124 times (remember lines 17 and 18) and then exits, returning control of the computer to the Basic interpreter. By using the technique of "emptying" the counting register every so often, one can overcome the problem of the 6502's 8-bit register. (Remember that an 8-bit register can only hold 256 different values.) The frequency information is contained in memory locations 254 and 255. These zero-page locations (so called because they are on the bottom 256-byte memory page) take less time for the computer to use: one less clock cycle per instruction.

```
]LIST

5  HOME
10  POKE 254,0: POKE 255,0
20  CALL 770
30 ZC =  PEEK (254) * 256 +  PEEK (255)
40 TF = ZC / 2
50 FRQ = TF * 1.0070801
60  VTAB 4: HTAB 27: PRINT "          "
70  VTAB 4: PRINT "THE FREQUENCY IN HERTZ IS "; INT (FRQ)
80  GOTO 10
```

Program listing 3.

Listing 3, the Basic program, clears the zero-cross count locations (line 10). It then calls the routine and calculates the number of zero crosses detected in the counting period. This figure is divided by 2 (line 40) to convert from zero crosses to cycles and multiplied by 1.0070801 to correct the count for a 1-second sampling period. Finally, since the fractional portion of the number isn't accurate, it is discarded, and the integer portion is displayed on the screen as the frequency in Hertz.

To enter the assembly-language portion of the program into the computer, enter the monitor with the command CALL-151 from Basic and enter the hexadecimal data from address 0302 to 0349 hex. After the information is typed in (consult the reference manual if you don't know how to enter hex data), save the information with the command: BSAVE PROG4.OBJ0,A$302,L79. You might wish to add the statement: 7 Print"BLOAD PROG4.OBJ0" to the Basic program in listing 3. This will ensure that the machine-language routines are loaded in each time the program is run. (Remember to put a CTRL-D before the BLOAD.)

I found this frequency-counting program to be quite useful. One of the first things I did with it was to measure receiver drift. With the program running, I turned my receiver's calibrator on and tuned the vfo until I heard a tone, which I fed into the Apple's cassette port. By noting the frequency of the tone when the rig was first turned on, and comparing it after a half hour, I was able to determine how many Hertz the receiver had drifted.

If the 1-second sampling time is too long for your needs, you can shorten it, sacrificing some resolution. For example, if you use a 1/100-second sampling rate, the result would be accurate to 100 Hertz. To accomplish this, change the 124 in line 17 of listing 2 to 12. This would make the sample time equal to 12 × 8192 clock cycles, or .00960938 seconds. Multiply by the reciprocal, 10.406494, and divide by 2 (or multiply by 2 and divide by the reciprocal) to get the frequency in Hertz. Obviously, any sampling time can be selected in steps of 8192 clock cycles. (Remember that the LOOP portion of the program always takes 32 × 256 or 8192 clock cycles to execute.)

Next month, we'll take a look at tone and waveform generation on computers. Keep the letters coming in—just remember to include an SASE.

REVIEW

THE KENWOOD MULTI-MODE TR-9500 TRANSCEIVER

Are those declining sunspot numbers making you think about a new challenge in the hobby for the coming years? Have you wondered about all that talk of the new OSCAR satellite and its fantastic DX potential? Or possibly a friend has told you about how interesting and sunspot-proof VHF/UHF propagation can be.

Well, a number of manufacturers have now extended the multi-mode-radio concept to the 70-cm band (420-450 MHz). These radios are ideal as a satellite uplink/downlink or for terrestrial DX as well. Kenwood's latest offering is the TR-9500 transceiver. This radio covers the frequency range of 430-440 MHz and provides FM, CW, and SSB modes.

(A word of caution to US and Canadian amateurs: Although the radio is accurately described as being multi-mode, the FM capabilities will not find much use here since present band plans place FM use in the 440-450-MHz portion of the band above the radio's band edge. Don't blame Kenwood for this, however; in most areas of the world, only the 430-440-MHz segment is allocated for all modes of amateur use, and most other radios on the market are similarly designed.)

The TR-9500 is a microprocessor-controlled unit complete with scanning, memories, and 10 Watts of rf power output. An optional base unit which includes a memory backup function, an external PS-20 power supply, and SP-120 speaker make it equally at home under the dash or on the operating table. It can be moved quickly from either thanks to its slide-in-type mobile mounting bracket. The 9500's 2m cousin is the very popular TR-9130, which makes an ideal companion radio, especially for OSCAR users.

In an approach similar to many state-of-the-art transceivers on the market, the TR-9500 employs a dual-vfo frequency-control system. For example, you could use vfo A for the 432-MHz portion and vfo B for 435-MHz and OSCAR activities. The radio does permit you to change frequency while transmitting—an important consideration for OSCAR users which has been overlooked on some other radios. Either vfo can be used to program the six memory channels. Once programmed, each memory channel can be recalled with a multiple-position switch or scanned automatically by the unit's microprocessor.

The Kenwood TR-9500.

Although such features are usually associated with FM operation, I found it useful both for OSCAR and terrestrial QSOs to keep tabs on band activity. During an OSCAR pass, you can program the beacon frequency in one memory and use the other memories for busy stations you hear and want to work. Just switch between channels and wait for the first QSO to end. I also used this technique during a contest.

For those who can make use of the FM capabilities, the TR-9500 is well equipped. Two standard repeater offsets, 5 MHz and 1.6 MHz, are provided as well as a programmable offset for the frequency programmed into memory channel 6. In this case, both transmit and receive frequencies are individually programmed for those odd split repeaters.

Now that we are familiar with some of the basics, let's sit down and actually go through the operation.

I push on the combination power switch and volume control and the bright green LED display shows 3.000.0 (for 433.000 MHz). This is the normal power-up frequency for vfo A. If the vfo B button were pushed, the unit would power up on 430.000 MHz.

I want to look around 432.1 MHz, so I depress the MHz button. This allows me to move one whole MHz for each click of the main-tuning knob. One complete revolution is 50 clicks, so I can move around the band pretty quickly. One click down puts me on 432.000, but now I have to move 100 kHz up in frequency. I push out the MHz button and now each click moves me 100 Hz. This will take a long time. The manual says that the FM2 position on the mode switch will provide steps of 1 kHz and the FM1 position, steps of 25 kHz. Hmmm. . . maybe this FM mode will be of some use after all. I quickly switch from USB to FM1; four clicks of the main-tuning knob and I'm on 432. 1 MHz. Sounds pretty quiet, so I try a CQ.

As I let go of the push-to-talk button on the mike, the back-light meter jumps to nearly full scale. It's my friend Glen K1GW. He sounds just a bit off frequency, so I depress the RIT button. A red LED lights to let me know the RIT is on and I tune him in a little better on the combination RIT/rf-gain control. We quickly get our frequencies netted and off goes the RIT. Glen gives me an excellent report both signal strength and audio.

I depress the power switch to the 1-Watt low-power position with equal readability at his end. We decide to QSY up 10 kHz to get off the calling frequency, but before I do I want to put the frequency into memory. I set the memory switch to position 1 and press the button right under it marked M. The radio beeps at me. I guess it wants to tell me I've done something important.

Let's see now, I have to move up to 432.110 MHz. If I tune the main-tuning knob, I should be there in about two revolutions (about 100 steps), or I can switch to the FM2 mode and be there in 10 steps. I opt for the latter. There's Glen and this time there are no netting problems.

We try it on CW for a while. The sidetone sounds good and is just about the

right level. My keyed signal is reported as clean. The TR-9500 uses the same filter for both SSB and CW. It also switches from a slow agc characteristic on SSB to a fast one on CW.

After we finish, I decide to explore further the scanning and memory features. First, I program in several channels at random. I depress the MR (Memory Recall) button and the channel selected on the memory switch is displayed. A green LED lights to tell me I'm in memory mode. Now I can switch between six channels just like on those old-fashioned radios from way back in the 1970s. Without crystals, of course. I depress the MS (Memory Scan) button and now I don't even have to touch the memory selector. The radio automatically steps through the channels, carefully jumping over those channels which are not programmed. When a signal is heard, the radio stops or stays put until you reinstate scan mode.

Next, we'll try scanning the vfo frequencies. I push out the MR button and the last frequency set on the vfo is displayed. Push the button marked SCAN and the vfo begins scanning up the band continuously in the normal steps according to the mode selected. I can stop it by pushing the HOLD button or the push-to-talk (PTT) button on the mike. Or it will stop automatically when it comes across a signal.

Speaking of the microphone, Kenwood has included an up/down remote-tuning feature which is especially useful for mobile use. Each push of the appropriate button moves you 1 step and lets you know with a beep. To QSY several steps, just count the beeps. Hold down either the up or down button continuously and the tuning rate increases—and so do the beeps.

During the evaluation period, I became quite proficient in using all those buttons and dials on the 9500 and found the radio to be functionally well thought out and a pleasure to use. On-the-air reports have been consistently good and no problems were encountered.

The manual provided is clear and concise, but it does not cover details of circuit design and repairs. There is an optional service manual available which presumably covers these details for those so inclined. I recommend to new owners of the radio that they thoroughly familiarize themselves with the operating manual in order to get the most out of the radio. Although operation is relatively simple, there are some sophisticated features which are not immediately obvious.

Only a couple of minor suggestions for future product revisions: There is no squelch function for SSB or CW operation, and although it's not a necessity as it is on FM, it would be handy. Also, I personally prefer the fast agc time constant even in SSB mode, and the automatic-switch feature did not allow me the option. I did appreciate the use of a type-N antenna. In a number of 70-cm radios on the market, this feature has been overlooked.

THE AEA INC. AMTOR TERMINAL UNIT

New modes of communication have always intrigued me. In past years, I have tried them all: RTTY, SSTV, high-speed CW, fast-scan TV, and even FAX. My favorite mode, by far, has been RTTY. If you are using a CRT, this mode can be completely silent. It also doesn't require continuous concentration, as does CW. One can step out of the shack for a minute and not miss a thing—every word will still be on the CRT.

Photo A. The AMTOR terminal unit from AEA, Inc.

While RTTY signals are fairly QRM resistant, noise and fading still can distort the copy, leaving a number of "hits" (the RTTY op's term for errors) in the printout. Now that computer-controlled circuitry has become more affordable, it only makes sense that someone would try to come up with a solid-state solution for detection and correction of transmission errors in RTTY communication. One method of accomplishing this is to use the AMTOR protocol.

AMTOR originally was developed for commercial users of RTTY. The AMTOR code is based on the Murray (Baudot) code and has the same character-set restrictions. Each AMTOR letter consists of seven bits arranged so that each letter has four 1 bits and three 0 bits. If, on the receiving end of the teletype circuit, a character is received that does not have the 4:3 ratio, an error has been detected.

AMTOR has two modes. In the first mode (ARQ), data are transmitted in blocks of three characters. If an error is detected by the receiving computer, it sends a control signal back that means "send the 3-character block again." If no errors were detected (all the characters had that 4:3 ratio), the receiving RTTY computer sends a character telling the sender to send the next three letters.

The second mode (FEC) has each letter sent twice. If an error is detected in one character, it ignores it and copies the other one. This mode does not require the transceiver to be constantly switching from transmit to receive.

AMTOR was implemented originally using mechanical devices, but as computer technology improved, it made sense to use microprocessors. Earlier this year, AMTOR was approved for use on the low bands (any digital code is legal above 50 MHz, but below it only AMTOR, ASCII, and the Baudot code), and various companies have started to support it.

The AMTOR AMT-1 terminal unit by AEA (Advanced Electronic Applications, Inc.) was designed to make it easy for a ham to use the AMTOR standard for RTTY. Consisting of a terminal unit, microcomputer, ROM software, and control circuitry in one integrated package, it makes AMTOR operation fairly automatic; all you have to do is add a computer with a serial port. When I first saw it, I was impressed by the modern design—there are absolutely no switches to be found on the unit! All control of the AMT-1 is accomplished by sending special character combinations through the serial port. The AMT-1 indicates its status via the LED display on the front panel and by sending special information back to the computer.

Setting the unit up takes a little while. In AMTOR operation, it is essential that the transceiver being used can switch from transmit to receive in 50 ms or less. (Remember that the TU takes care of T/R switching and has to switch back and *forth between every three characters.)* The shorter the T/R switching time, the better: Maximum distance is limited by too long a switching time. My TS-520S just made it. I would imagine that most new solid-state rigs would have absolutely no problems. The AMT-1 connects to the rig's microphone jack, the PTT lines, and the audio output (Photo A). It is convenient to tap the audio from the rig at a point before the volume control. This allows adjusting the rig's audio without disturbing the AMT-1.

Connecting a computer to the AMT-1 requires an RS-232-compatible port set to either 75 or 110 baud, full duplex. It is important to have the full-duplex mode because the unit echoes back as soon as any characters are typed (this can be disabled, but it is better to use the AMT-1 echo feature). AEA included two DIP jumper plugs which bypass the TTL to RS-232 conversion circuitry. While this is mainly for VIC-20 and Commodore-64 computers which use TTL level signals in their serial ports, it can be used in conjunction with other micros. I was able to write a program for my Apple II which "converted" the game port to a full-duplex serial port. After wiring up an appropriate connecter, I plugged in the AMT-1 and it worked flawlessly.

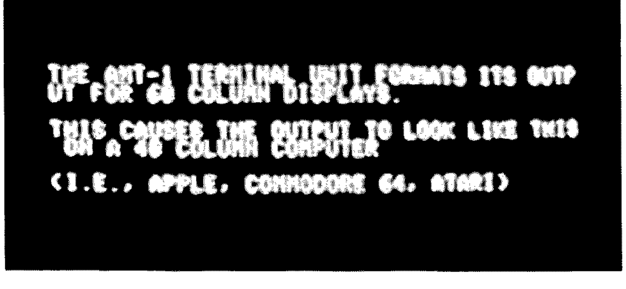

Photo B. AMT-1 output display sample on a 40-column computer.

The AMT-1 provides for word wraparound, but only for terminals that are over 60 columns wide. On a 40-column computer, the display looks a bit strange. (See Photo B.) Fortunately this can be disabled, causing the text to go from one end of the screen to another. If you want word wraparound for a 40-column machine, you can provide for it easily in software. Many terminal control programs incorporate this feature already. While a custom program might provide the most flexibility for using the AMT-1, any terminal communications package that allows control characters and escape characters to be transmitted should do the trick.

When first turned on, the AMT-1 goes through a testing sequence that causes all the LEDs to turn on and off in a pattern. (I don't know if that accomplishes anything, but it looks nice.) It then enters the "escape mode" and is ready to accept a command from the computer. Typing a Q gives the unit's status:

V:03 I:???? T:30 B:45 S:20 L:1 N:1

The V is the revision number of the software. Mine is revision #3. I is for the selcal code. When nothing has been entered, it shows question marks. T is the AMTOR ARQ timeout: how long the unit should wait to receive the confirmation character before indicating an error. B is the baud rate for conventional RTTY operation (the unit also works nicely for "regular" RTTY). S is the CW sending speed, and L and N refer to word-wrap and echo-back modes.

To change a parameter, one types an ESC character followed by the proper letter. For example, to put the selcal code AFTM (no numbers are allowed) in memory, type ESC I. The unit will prompt with a *colon, after which you enter a four-letter* code of your choice. All the other parameters are changed in much the same way.

After I got through the 16 pages of documentation and wired up all the necessary cables, I tried it out on the air using the Baudot mode. One thing about this TU that took a bit of getting used to is the fact that it copies "upside down"; the receiver must be set for USB instead of the more traditional LSG. There is no disadvantage to doing things this way; it's just different from the way most terminal units operate.

Tuning around 20 meters, I found the TU to be fairly good. It uses an unconventional design: The audio is fed through a 4-stage active 300-Hz bandpass filter and then to a frequency-to-voltage converter. This is to facilitate a bar-code-tuning display. Tuning in a signal is easy; the receiver is tuned until one sees a centered pair of flashing LEDs on the display.

Before actually trying an AMTOR QSO, I decided to try copying the ARRL AMTOR bulletin. The League transmits their RTTY bulletin in the FEC (forward error-correction) mode—the one where each letter is transmitted twice. Absolutely flawless copy was the result; the same bulletin I copied using the Baudot mode did have a number of hits.

Most AMTOR activity is centered around 14.075. I went to this frequency and called CQ in the FEC mode. (It is usual practice to call CQ in the FEC mode and switch to the ARQ mode once communi-

cation has been established.) There was no reply. I tried again in a few days when the band conditions improved and met with success—I contacted WB2VTN running AMTOR on an IBM-PC using a home-brew interface.

The copy was flawless. Not a single error (except typographical ones) appeared on the copy. The ARQ mode—the one which waits until the other station's computer acknowledges correct reception of the data before sending more data—makes it very difficult for an error to creep through. Of course, if the band dies out completely, both stations will be waiting forever for the other station to reply (although, I would imagine, one would catch on after a little while). Just as with any other mode, if the signal isn't there, it can't be copied. But if conditions are bad and copy would be rough with conventional RTTY, AMTOR can get through—it would just slow down a bit.

Unfortunately, there isn't (as of this writing) much in the way of software support for the unit. Although one can probably get by nicely with a standard modem control program, it is nice to have a custom-tailored ham-radio communications program. Be sure you have the necessary programming skills to control your computer's RS-232 serial port (this can often be done easily in Basic). I was able to get the AMT-1 running on an Apple II, an Atari 400, and an IBM-PC without too much difficulty. Certainly, the necessary computer programming is well within the abilities of even the most casual computer hobbyist.

Based aroung a 6800 microprocessor, the AMT-1 is of sound design. All the parts are off-the-shelf TTL and linear. The metal enclosure effectively shields out any RFI that the TTL circuitry might generate. I was able to dectect absolutely no RFI on a receiver a few inches from the unit.

I found the AEA AMT-1 a pleasure to use. Not only did it make the transition to AMTOR easy to implement, but also it made conventional RTTY more enjoyable. Because the unit controls T/R switching, you can run KOX (Keyboard-Operated Transmitter). All you have to do to switch from transmit to receive is start typing. Oh, yes . . . the unit also sends CW at any speed from 1 to 100 wpm for those of you who still like to do things the "old-fashioned" way.

ELECTRONICS IN YOUR POCKET

When I think of all the books I used to study for my "ticket," I just marvel at the fact that anything worthwhile ever happened. I used several college texts, license study guides, reference books, and stacks of back issues of *73*. I really wanted to be successful in my venture. One thing I immediately learned is that too much information can be just as bad as too little. This idea is universal, whether you are studying to pass a test or just want to build a simple circuit. The main key is in limiting your resources to a few that you can really study; forget the library approach.

There are literally hundreds of good reference books on the market. The real problem is that the total number of these books is growing at an alarming rate. This leaves the average, uninformed, "I-want-to-learn-ham-radio-on-my-own" person with a very difficult problem. How does a person cut through the glut of electronic reference books and select the one which will do the most good? Well, one thing which I will not attempt is to tell everyone which is the best. Instead, I will tell you about one text which has helped me in my work as an engineering technician and as a ham.

The book to which I'm referring is *Electronics Pocket Handbook*, by Daniel L. Metzger. I will briefly describe this book, pointing out various aspects, good and bad, which I've encountered while using it. The *Electronics Pocket Handbook* is exactly that. It is just slightly longer than a 3" × 5" index card and not quite as wide. The size makes it ideal for briefcase, coat pocket, or purse. You don't have to worry about all the pounds of books usually associated with study.

The book is sectioned into seven separate chapters and an index. Chapter 1, "Definitions, Formulas, and Charts," contains information very similar to that found in the *ARRL Handbook*. It gives you information on Ohm's Law, inductors, capacitors, complex notation, power-supply formulas, etc. Other information which isn't so typical in this section is on Boolean formulas and thermal, geometric, and bridge formulas. These latter formulas can be very difficult for the lay person to pin down when needed.

Some very needed component information is contained in Chapter 2. The title, "Component Data and Characteristics," says it all. This chapter contains information on wire insulation, wire characteristics, popular connectors, conductivity of various conductors, color codes for resistors, capacitors, and inductors, etc. You will learn how to read component values from any passive component, whether vintage 1932 or 1983. You also will learn how to read MIL-STD resistor designations such as those used on NASA surplus boards. This chapter can provide the individual with new knowledge which can help refine his ability as a scavenger. If the information in this chapter is actively applied when purchasing from the surplus market, a great savings should be realized.

In Chapter 3, "Simplified Circuit Analysis and Design," we start getting into the meat of electronic theory. You will work with resistive circuits, learn about several popular network theorems such as Thevenin's, Norton's, and Millman's, and the reciprocity theorem. You also will get into general circuit analysis, nodal analysis, and ac circuit analysis. In spite of the fact that some of these names may sound a bit scary, don't worry. The author has tried to make these as painless as possible and still maintain some authority in the text. If this information is not enough, you will also find transistor-biasing formulas and a small section on op-amp design. This is a good section to work through to help prepare your mind for any type of circuit analysis. *Especially on tests!*

In Chapter 4, "Units, Conversions, and Constants," we are introduced to the international system of units—Systeme Internationale d'Unites (SI). This is the system which the international engineering community has adopted as a standard. This chapter goes into detail on the various aspects of the system. You will learn shortcuts and keys which will enable you to use the system more efficiently. In addition to this, you will learn how to perform various unit conversions, such as quarts to liters or meters to feet. There is also a section on the most-frequently-used constants from science. These aren't all pertaining to electronics. This particular chapter has quite an appeal to all students of the sciences.

In Chapter 5, "Standards, Symbols, and Codes," you will learn about broadcasting frequency standards, wavelengths, electrical wiring practices, hardware standards, etc. Included in the mechanical section is information on drill sizes, metal gauges, and general hardware tidbits. There is also a review (briefly) of teleprinter codes such as Baudot and ASCII. Sorry, no SITOR or AMTOR in this section. If some readers are still latent CB hounds, then the 10-code listing should prove useful for them. This chapter, especially the hardware information, should be interesting to the avid home-brewer.

In Chapter 6, "Test Procedures," you will learn how to test meters, batteries, inductors, capacitors, inductor Q, and resistors. You will learn the ins and outs of semiconductor testing and even get into the mechanics of amplifier testing. If home-brew isn't really your bag, you still could do well to read this even if you only occasionally service your rig.

Finally, in Chapter 7, "Glossary of Electronic Terms," we have a very comprehensive listing containing most of the commonly-used technical terms. This should be especially appealing to the newcomer. This will help give everyone an understanding, even if only rudimentary, of a term and its various associations. Several popular books neglect including this kind of information. They treat it as an unnecessary option. I disagree with that line of thinking totally. This little text has a full sixteen pages of definitions and terms which are extremely useful as well as educational.

Another aspect of this book which I like is the index. Most people, including several new technical writers, take this section of a book for granted. It is very frustrating when you need to find something in a hurry and it takes an hour. The lack of an index is a good indication that the author really doesn't care about the readers at all. This isn't the case with this book. The index could stand to be a little more comprehensive, but the book is organized in such a manner that finding most subjects is easy anyway.

Electronics Pocket Handbook is published by Prentice-Hall, Inc. In case you want your local bookstore to order you a copy, the ISBN number is: 0-13-251835-X. (This usually is needed when they have to place a special order.) You can expect to pay about nine dollars for this. In my opinion, it is probably the best nine-dollar investment I've made in quite a while. Now I can think about upgrading no matter where I may be. This is an excellent companion on trips when you can't carry tons of regular references with you.

Hiawatha IA

THE PRIVATE PATCH BY CONNECT SYSTEMS

The Private Patch II, by Connect Systems, is perhaps the most sophisticated simplex autopatch yet to hit the market. Hook the Private Patch up to an FM transceiver and a telephone and you're on the air with your own autopatch. It puts a simplex patch, control system, and CW IDer all in one box.

This patch is different from the other simplex patches on the market because it uses a VOX circuit for control rather than a sampling system. Most simplex patches are designed to switch the transmitter off every few seconds to quickly sample the receiver input. Since the system is simplex (it's either talking or listening, but not both at once), that's the only way they can tell if a mobile station wants to talk—if a carrier is present during the sampling period, the system stays in receive mode to allow the mobile to talk.

The sampling method works, but it has two disadvantages. First, it's annoying to listen to the squelch tails that are generated every time the unit samples. Second, and more important, the transceiver used with a sampling system has to be able to switch between transmit and receive very rapidly. That means that radios with relay switching won't work, and most radios will need modifications to speed up the action of the squelch circuit.

The Private Patch II avoids these problems by using a sophisticated VOX circuit to control T/R switching. If the party on the telephone stops talking for more than about a half second, the unit switches from transmit to receive. The mobile unit can break in during the normal pauses that occur in conversation. To provide backup control, if the unit stays in transmit mode for more than about 20 seconds, it automatically goes back to receive for about 3 seconds. Thus, the mobile user will never be locked out for more than 20 seconds.

The VOX switching system also allows the Private Patch to work through repeaters since the repeater carrier won't lock the system into receive mode. Because the transceiver switches less often and stays in the receive mode longer, the stringent T/R-switching requirements of sampling-type patches are avoided.

The only disadvantage of the VOX switching system in the Private Patch is that mobile access is also VOX controlled. In other words, you can't capture the system merely by mashing down on the mike button. You actually have to say something before you're in control

The Private Patch II works very well. It took only a few minutes to get everything hooked up to my Midland 220-MHz radio, and no internal modifications to the radio were necessary—all the connection points were available on the back panel of the Midland. The Private Patch needs only microphone, keying line, and speaker audio connections.

I did have one problem with the unit—the Midland T/R relay draws over 100 milliamps, and a power surge when the relay closed fried the switching transistor in the Private Patch the first time the transmitter switched on. The Midland relay probably draws more current than the average, so this problem shouldn't commonly occur, and the factory reports that they know of no other such failures. My solution was to use the keying circuit to drive a smaller reed relay which in turn drives the T/R relay.

Once the keying problem was taken care of, the Private Patch played well. It was very easy to adjust the audio-level controls to get the proper volume levels, and everyone who used the unit (both radio and landline users) commented on the good audio quality.

The patch has a built-in tone decoder, and control codes are provided for access, disconnect, and timer-reset functions. Front-panel switches allow long-distance dial restriction (by shutting the patch off if the first number dialed is a 1 or 0) and ringback enable and disable.

If the ringback circuit is enabled, the unit will operate as a reverse autopatch. When the telephone rings, the Private Patch will identify once and the telephone can be answered by sending the timer-reset code. The system then works as if a normal autopatch call had been placed.

A lot of thought went into the design of the Private Patch II. Many features that

aren't strictly necessary but are sure nice to have are included. For example, the IDer operates during the last minute before timeout so that the mobile operator has plenty of advance warning to reset the timer. The access codes can be changed to protect system security.

The reverse-patch ringback is disabled if a QSO has been in progress on the channel within the last few moments (so you won't get other users of the channel upset with your machine). A tone-to-rotary converter is built in so that the patch will work on any phone line.

All in all, the Private Patch II is quite an amazing box. The VOX switching system makes it unique, and it has all the other features necessary to make it a thoroughly practical machine. For more information, contact *Connect Systems, PO Box 4155, Torrance CA 90510; (213)-540-1053.*

John Ackermann AG9V
Green Bay WI

THE TR-720 VHF TRANSCEIVER

Many hams and readers of *73* are pilots and aircraft owners. Therefore, this month we present a review that deals with an AM transceiver for use on the 118-136-MHz aircraft band. We think that this unit will find much favor with pilots because of its small size, light weight, and extreme portability, providing a versatility seldom seen in aircraft equipment, with little if any sacrifice in performance.

One of life's nicer surprises is to find a piece of equipment that performs *better* than you expected. The TR-720 aircraft-band VHF transceiver is one of these; it is a joy to own and operate.

Although Communications Specialists is well known for its line of amateur and commercial encoders and decoders, it is less well known for its other products...including this new venture into two-way communications equipment for the aircraft owner and pilot...and it is a real pleasure to find that the equipment is almost ideally suited to fill a real need.

The VHF aircraft band extends from 118 MHz to 136 MHz and—unlike other VHF communications services—it is AM, not FM. In the frequencies encompassed by this band, there exist 200 navigation "channels" and 720 communications "channels."

The navigation channels are occupied by VORs (ground-located VHF Omni Ranges), stations which permit a pilot to home in from any point of the compass by means of an instrument mounted on the instrument panel. All the pilot needs to do is tune in the station, center the needle by turning the OBS (Omni Bearing Selector), and then fly the plane on that bearing so that the needle remains centered.

This, of course, is an oversimplification, but it will serve to describe one general way in which the VOR system is used. The instrument tells the pilot whether the radial that he is on is *To* or *From* the station (there are 360 radials...one for each full degree of the compass). When the plane passes over the station, the "To-From card" flips over.

While the pilot flies the needle, he also can listen to the VOR station itself and receive the Morse-code indentifier plus voice transmissions of weather and other information needed to fly safely to his destination.

The 720 communications channels are used for the purpose of talking to airport control towers, Unicom stations, other aircraft, Flight Service Stations, and the like. It was the advent of equipment having superior selectivity and frequency stability that made possible the increase in the number of communications channels from 90 to 360 and then to 720...permitting expansion and growth of the system to meet current needs.

SPECIFICATIONS

Model	TR-720 airband transceiver
Frequency range	118.000 MHz-135.975 MHz (Com band), receive and transmit 108.000 MHz-117.975 MHz (Nav band), receive only
Number of channels	720 (Com band) with 25-kHz spacing 200 (Nav band) with 50-kHz spacing
Frequency determination	Microprocessor-controlled CMOS phase-locked loop
Frequency stability	±.001% (−10° C to +60° C) ±.002% (−30° C to +80° C)
Power consumption	39 mA squelched 185 mA @ 300 mW audio output 650 mA transmit
Antenna type	Flexible rubber 50-Ohm unbalanced type
Battery type	9.6-V/450-mAh nicad battery pack (CS-15), or 9.6-V/750-mAh nicad battery pack (CS-18), or 12-V, 8 AA alkaline batteries (CS-19)
Size	6.6" (169 mm) x 2.6" (64 mm) x 1.5" (38 mm)
Weight	1.2 lb. (19 oz./.544 kg) with battery
RECEIVER	
Receiver type	Dual conversion superheterodyne
Sensitivity	Less than .5 uV for 10 dB (S+N)/N (Com band) Less than 2 uV for 10 dB (S+N)/N (Nav band)
Selectivity	60 dB at 25 kHz
Squelch sensitivity	.5-uV threshold, FM noise type
Audio output	500 mW maximum, less than 10% THD
I-f image rejection	Greater than 60 dB
Spurious response	Greater than 60 dB
TRANSMITTER	
Rf output power	1 Watt nominal, 800 mW minimum, 3 Watts PEP into 50-Ohm load
Frequency stability	±.002% (−30° C to +60° C)
Spurious & harmonics	Greater than 60 dB below carrier
Modulation type	6A3, high level Class B collector modulation (AM)

Most of the users of larger aircraft, including the airlines, corporate fleets, and the like, have several sets of VHF communications and navigation radios on each airplane. Some are redundant, for safety's sake, while others are needed for simultaneous reception/transmission and navigation. All of the equipment is expensive, and much of it is beyond the financial reach of many private pilots and aircraft owners who fly for fun. As a consequence, many smaller airplanes have only one radio: a Navcom unit that combines both functions of communications and navigation. Often, these radios are older tube types and are limited in channel spacing to only 90 or 360 channels, thus limiting—or even prohibiting—many smaller, privately-owned aircraft from full use and enjoyment of the national air-traffic system.

Pilots of sailplanes (gliders), balloons, experimental and home-built aircraft, firefighters, ultralights, and other types of aircraft may have a sometime need for VHF communications and navigation radios and often cannot or will not spend the larger amounts of money required for permanent installation of expensive equipment.

Communications Specialists, recognizing the need in this area for small, lightweight, inexpensive rigs, has introduced to the marketplace its new TR-720, a handheld transceiver of outstanding performance. Here is a unit that is crystal-synthesized to cover all 720 communications channels and 200 navigation channels; it operates on an internal nicad battery pack which can be recharged from either an automobile or aircraft dc supply of between 12 and 28 volts or from the 115-volt-ac house mains. Further, and still more convenient, the TR-720 has the standard aircraft BNC connector for its antenna. Thus, a coaxial cable may be connected from the aircraft antenna, or the standard flexible (rubber ducky) supplied with the unit may be used.

Just a tiny handful, weighing only 1.2 pounds with the standard nicad battery pack, and measuring 6.6 × 2.6 × 1.5 inches, the TR-720 has giant-size performance. Receiver sensitivity is exceptional, and power output on transmit is nominally 1 Watt dc or 3 Watts PEP, voice modulated. An adapter for an external microphone and headset is provided for those who prefer them for use in the cockpit. One of the prime advantages of a transceiver operated from its own supply is the obvious backup capability it provides in case of failure of the aircraft radio system. Almost as important is the capability of portable operation, where FAA (Federal Aviation Agency) personnel may need to direct traffic from an emergency runway, a helicopter landing pad, or another location where no permanent radio installation exists.

The pilot of a sailplane, which often has no permanent battery or radio setup, would find the TR-720 ideal for his purposes...for contacting the tower at a controlled airport, for example, when wishing to land. The TR-720 is easily and handily carried aboard and mounted by means of its belt loop on the leather carrying case. It can be suspended from the belt, of course, and carried portable in that manner as well. One can visualize stuffing the hand-held into an available glove box (it fits into the glove compartment on my Cessna 150 with plenty of room to spare) or mounting it temporarily somewhere in the vicinity of the instrument panel for quick reference and use.

I was very surprised to find that the TR-720 was hearing stations in flight better than my standard aircraft radio—which, by the way, is one of the older 90-channel types, unable to receive or transmit on the split frequencies in common use today. Thus, for me, the TR-720 allows access to airports and FAA communications facilities that I could not otherwise use.

The TR-720 receives even distant stations on its flexible antenna *inside* the cabin of my all-aluminum Cessna. I have not yet found the need to use the aircraft external antenna for receiving, but I have discovered that it works best on the hand-held for transmitting to distant stations...as you would expect, considering the amount of output power.

Enjoying the TR-720's internal battery pack and its isolation from the aircraft electrical system, I find that much of the hash generated by my engine and its accessories is absent when I try to hear another station. This means that I don't have to ask for a repeat of the transmission, and it certainly saves wear and tear on the ears. I seem to be approaching the situation where I plan to use the TR-720 as my main transceiver for communications and my aircraft radio for navigation only!

I took the TR-720 on vacation with me and found that it attracted attention wherever I went. One FBO (fixed base operator) told me that it was "...the best-sounding radio on the field!" Another told me that he wanted to stock them for his local clientele and for transient visitors to his field. The pilots themselves are really interested, and two local pilots who fly a lot of formation with their Piper Cubs want a pair of them for plane-to-plane communications.

Civil Air Patrol personnel would find these units ideal for search-and-rescue operations. In particular, a recent airplane crash at a remote mountaintop site required ground search teams. Their work and coordination from aircraft in the area might have been greatly simplified and speeded up had some TR-720s been available.

One of the features you will like is the twist-off battery pack, permitting almost instant replacement by a fresh pack when needed, while the original pack is being recharged. Battery packs of 450-milliampere-hour capacity are standard, but 750-mAh packs are available. Supplied accessories include: flex antenna (rubber ducky), simulated leather case, 115-V-ac wall charger, dc charger (cigarette-lighter-adapter plug), earphone, and operating manual. Available accessories are: alkaline battery pack (batteries not supplied), nicad rapid charger (1 hour), desk-type drop-in charger, 220-V-ac wall charger, simulated leather case for use with larger battery pack, remote hand-held speaker/mike, cable adapter for PJ-068 and PJ-055 to TR-720, and cable adapter for U-174 to TR-720.

An outstanding feature of the TR-720 that I have not seen on similar units for aircraft-band use is the 3-position memory. You can store three different frequencies in the memory merely by setting them, one at a time, on the dial, switching to memory locations 1, 2, or 3, and pushing the memory-store button. This way, for example, you could set up in advance an ATIS frequency, a control-tower frequency, and a ground-control frequency. Perhaps you might want approach-control, tower, and

departure-control frequencies. Another possibility would be the split-frequency or half-duplex option where you set a Nav frequency (VOR, for example) into memory and a Com frequency on the dial. Then you can communicate with a Flight Service Station and hear its reply over the VOR station closest to your location.

Frequency selection is by thumbwheel dials, and a noise-type squelch circuit as used on FM equipment is incorporated so that you don't have to listen to "white noise" between transmissions. This saves the battery, too.

The TR-720 employs 1 microprocessor, 10 integrated circuits, and 50 transistors. Transmitter and receiver incorporate 12 varactor-tuned stages which track with the selected frequency for optimum performance from band-edge to band-edge. The TR-720 is FCC Type Accepted (US) and DOT Certified (Canada).

Communications Specialists places a 1-year warranty on the TR-720, with a guaranteed 72-hour turnaround for repair or replacement.

Aircraft owner's net price is $795, including the standard supplied accessories described above. For further information, call or write *Communications Specialists, 426 West Taft Avenue, Orange CA 92665-4296; (800)-854-0547; (714) 998-3021.* Dealer inquiries invited. Reader Service number 485.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL SWEEPSTAKES CW

Starts: 2100 GMT November 5
Ends: 0300 GMT November 7

Phone

Starts: 2100 GMT November 19
Ends: 0300 GMT November 21

US and Canadian stations work other US and Canadian stations using the 1.8- through 28-MHz bands, excluding 10 MHz. Operate no more than 24 of the 30 hours with on/off times noted clearly in your log. Listening time counts as operating time. Operating categories include single-operator and multi-operator with a single transmitter.

No cross-mode contacts will be allowed and each station can only be worked once, regardless of frequency band. A transmitter used to contact one or more stations may not subsequently be used under any other call during the contest period (with the exception of family stations where more than one callsign is assigned by FCC/DOC). One operator may not use more than one callsign from any given location during the contest period. The use of two or more transmitters simultaneously is not allowed.

EXCHANGE:

Consecutive serial number, precedence (A if you run 150-W output or less, B if more than 150 W), your callsign, check (last two digits of the year you were first licensed), and your ARRL section.

FREQUENCIES:

CW: 1800-1810, 3550-3650, 7050-7100, 14050-14100, 21050-21100, 28050-28100.

Novice: 3710, 7110, 21110, 28110.

Phone: 1855-1865, 3850-3950, 7200-7250, 14250-14300, 21300-21400, 28550-28650.

SCORING:

Count 2 points for each completed 2-way QSO. Multipliers are each ARRL section plus VE8/VY1 (74 maximum). KP4, KV4/KP2, and KG4 stations are in West Indies section, while KH6 and other US possessions in the Pacific count as the Pacific section. Final score is QSO points times the number of ARRL sections (plus VE8/VY1).

AWARDS:

Certificates to the top single-operator CW and phone scorers in both the A and B categories in each ARRL section, and the top multi-operator entry in each ARRL Division.

ENTRIES:

Contest forms (log sheets, summary sheet, dupe sheet) are available from ARRL HQ for an SASE. Official forms are recommended. Any entry claiming more than 200 QSOs must submit duplicate checking sheets. Incomplete or late entries will be classified as checklogs. Logs should include dates, QSO times, exchange sent/received, band, and mode. Postmark your entry for either mode by December 21 and send it to: ARRL, Newington CT 06111.

Each entrant agrees to be bound by the provisions as well as the intent of the official ARRL rules, the regulations of his licensing authority, and the decisions of the ARRL Awards Committee. The usual disqualification rules apply.

INTERNATIONAL POLICE ASSOCIATION CONTEST

0000-0300, 0700-1000, 1400-1800 GMT
November 5-6

Sponsored by the IPARC, this contest will be conducted on both CW and phone.

EXCHANGE:

Signal report and serial number. US stations also send state; IPA member send "IPA."

FREQUENCIES:

Phone: 3.650, 3.775-3.8, 7.075, 14.295, 21.295, 28.650.

CW: 3.575, 7.025, 14.075, 21.075, 28.075.

SCORING:

Non-IPA stations can work IPA members only, and each station can only be worked once per band. 4 points per QSO on 20, 15, and 10 meters. Each QSO on 40 and 80 meters counts two points, except DX, which is worth 8 points per QSO.

ENTRIES:

Mail entries by December 31 to: Anton Kohten DK5JA, PO Box 40 01 63, 4152 Kempen 1, Federal Republic of Germany.

RESULTS

I5NPH, 4M3AZC, K3TUP, AND KC5NQ: 1983 WORLD 40-METER CHAMPS

Multi-band contests are won or lost on the 40-meter band! All the top contest stations will admit that a decent score on 7 MHz may spell the difference between first- and second-place finishers. Why is it, then, that 40 seems to be the forgotten band by so many? The answer is *congestion!*

Broadcast signals make for a very hectic experience if one is to roost on 40. That is why *73* recognized the rare opportunity to prove that 40 meters can in fact be the born-again band it used to be. With all the elements against you, the top contester would be the one who could survive the strong carriers of AM broadcast stations overseas, the sometimes unbearable QRN that even the best filter cannot overcome. To top that, to obtain those necessary multiplier points, here's a band that tests your skill in crossband operation once and for all.

The majority of contestants indicated that the DX paths were excellent to most parts of the world, particularly to Europe and Asia. Stations added a host of new countries to their DX tallies! Stateside conditions were reported to be the best they had been in many weeks.

After all the smoke had cleared and the entries were received and tallied, KC5NQ led the pack for single-operator stations. This championship station managed 756 QSOs in less than 16 hours of 40-meter operation and worked 61 states and provinces and 45 DX countries. A distant second was afforded Florida contester N4BAA, who accumulated 559 QSOs, 55 states and provinces, and 48 countries. For single-operator DX stations, our good friend 4M3AZC of Venezuela became the world champ with 578 QSOs, 53 states and provinces, and 56 DX countries for his total. K3TUP took top honors for all W/VE multi-operator stations with a super tally of 1214 QSOs, 58 states and provinces, and 56 DX countries. DX multi-operator honors went to I5NPH, who worked 667 QSOs, 43 states and provinces, and 64 DX countries.

Of all the classes and categories in the 40-meter contest, the W/VE multi-operator final heat was the closest. Close on the heels of champion K3TUP was 160-meter contest winner K8ND with 1129 QSOs, 57 states and provinces, and 37 DX countries. Only 85 QSOs and roughly 6,500 points separated these first- and second-place finishers.

In the W/VE single-operator class, stations with 500 or more QSOs were KC5NQ (756), KA1XN (718), KC3N (702), KG1E (676), KM9P (618), K4HAV (617), KC8JH (600), WA0IDK (590), N4BAA (559), KA1GHR (523), WA4SVO (506), and KA1WJ (503). DX single-operator stations with 400 or more QSOs included 4M3AZC (578), IO3MAU (478), IO6NOA (438), OK1TN (438), and CT4NH (426). In the multi-operator class, 500 or more QSOs were obtained by K3TUP (1214), K8ND (1129), K5LZO (813), KC0SZ (764), I5NPH (667), I4OUT (648), N8EKE (592), and KB0QA (584).

Well over 50% of the 40-meter contestants worked 40 or more states and provinces, many stating that they worked all states in the 24 hours of the contest period. KC4NQ managed to get a clean sweep of 61 state and provincial multipliers, the only one in the contest to get all W/VE multipliers possible. KA1XN lacked only 2 to match KC5NQ's feat, while KC8JH, VE3ICR, K3TUP, and KC0SZ all recorded 58 out of the 61 possible states and provinces.

In DX, the following stations worked 30 or more DX countries: I5NPH (64), I4OUT (62), OK1TN (59), 4M3AZC (56), IO6NOA (56), IO3MAU (50), N4BAA (48), CT4NH (47), KC5NQ (45), VE3ICR (42), PY5EG (41), DL8NBE (41), OK1AYP (38), K8ND (37), DA1TN (37), KG1E (36), K5LZO (35), KC0SZ (33), VO2CW (32), KA1GHR (32), KA1WJ (32), and KA2CDE (31).

With January just around the corner, it's time to prune those dipoles and inverted vees and get ready for the 3rd annual event. If propagation is in our favor and we can get the word out to as many DX stations as possible, we expect to see some fantastic scores and some new world records!

You still have time, so send in your 1984 contest forms today! Enclose an SASE and send your request to Dennis Younker NE6I, 40-Meter Contest Chairman, 43261 Sixth Street East, Lancaster CA 93535.—*Bill Gosney KE7C*

40-METER CONTEST SOAPBOX

KG1E: "Will try a beam next year instead of a dipole at 50 feet!"

KA1RC: "A great contest. New delta loop worked well on DX. Blew the linear halfway through the contest though. Will definitely be back next year despite problems this time around."

KC3N: "Working 35 DX stations split frequency without an external vfo gives one fast fingers! Loads of fun but couldn't the broadcast stations QSY? Age 16. See you next year."

K3TUP: "24 hours is a perfect amount of time for any contest."

WA3SPJ: "Enjoyed both 40- and 80-Meter Contests a lot."

N4BAA: "Great contest again! Next year will have 4 elements at 140 feet."

WC4E: "Thank you, *73*, for the opportunity to participate in such a fine contest."

WD4RCO: "Most enjoyable contest. Good representation of DX, most of whom willingly listened up."

W4TMR: "This is my first 40-Meter Contest, can't wait until next year!"

KC5NQ: "The DX was better this year and the band was in extremely good shape. Thank you, *73* and the contest bunch."

N7BUP: "Had a great time—wish I had better prepared to go the distance overnight."

KC7PA: "Next year, I definitely am getting a second vfo. Hate to miss the rare DX. Got five new countries, however. How about a low-power category next year? Otherwise, I'll need an amp."

K9GDF: "My wife (N9DIJ) almost beat me in this contest."

KC0SZ: "Would have been nice to have Europeans listening upband. We had several openings but no one would listen up frequency, it seemed."

EA1QF: "A great opportunity to work new states or countries."

HI8GB: "Thanks very much for an interesting phone contest—it's long overdue!"

IO6NOA: "I expected more participation from Europeans. Many asked what contest was going on."

VE3ICR: "Didn't expect to be so involved in the contest. However, once I started, it was hard to quit!"

40-METER ANTENNA SURVEY

	1982	1983			
			Delta loop	9.3	3.8

DARC CORONA 10-METER RTTY CONTEST

Starts: 1100 GMT November 6
Ends: 1700 GMT November 6

This is the last of four tests during the year sponsored by the DARC eV to promote RTTY activity on the 10-meter band. Use the recommended portions of the 10-meter band. Each station can be contacted only once. Operating classes include single-/multi-operator and SWL printer.

EXCHANGE:

Each completed 2 x RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists, each US state, and each district in VE/VO and VK. The final score is the total QSO points times the total multiplier.

AWARDS:

Appropriate awards to the leading stations in each classification, assuming reasonable scores.

ENTRIES:

Logs must contain name, call, and full address of participants. Also show class, times in GMT, exchange, and final score. SWLs apply the rules accordingly. Logs must be received within 30 days after the test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

DELAWARE QSO PARTY

Starts: 1700 GMT November 12
Ends: 2300 GMT November 13

Sponsored by the Delaware ARC. Stations may be worked once per band and mode for QSO and multiplier credits.

EXCHANGE:

CW—1805, 3570, 7070, 14070, 21070, 28070.

SSB—1815, 3975, 7275, 14325, 21425, 28650.

Novice—3710, 7120, 21120, 28120.

SCORING:

Delaware stations score 1 point per QSO. Multiply total by the number of ARRL sections and DX countries worked.

Others score 5 points per Delaware station worked. Multiply total by the number of Delaware counties worked on each band and each mode (maximum of 36 multipliers possible).

ENTRIES AND AWARDS:

Appropriate awards will be given to the top scorers. In addition, a certificate will be given to all stations working all three Delaware counties. If you work all three counties and want the WDEL Award, send two 20-cent stamps and an address label.

Mail logs by December 16 to: Charlie Sculley AE3H, 103 E. Van Buren Avenue New Castle DE 19720. Send an SASE for a copy of the results.

OMISS QSO PARTY

Starts: 0000 GMT November 12
Ends: 2400 GMT November 12

Sponsored by the Old Man International Sideband Society. Work stations once per band. Exchange RS, name, state, and OM number (if any). Count 5 points per OMISS member, 2 points per nonmember. Multiply by total states, VE provinces, and DX countries. Plaque to top-scoring member and nonmember. Certificate to top-scoring members in each US call district. Mail logs and cover sheet within 15 days to: Rich Besitka KA1HGY, 480-B Radmere Road, Cheshire CT 06410. Include an SASE for further information.

CQWE CONTEST

Starts: 1900 GMT November 12
Ends: 0500 GMT November 14

Sponsored by the Bell System Amateur Radio fraternity, the contest contains various sessions during the period. The contest is open to present and retired employees of Bell, Western Electric, AT&T, and subsidiaries of AT&T. Contact your local interworks coordinator for logs and complete rules, or write to: Phil Pearson WA1LXY, Bell Telephone Laboratories, 1600 Osgood St., North Andover MA 01845, Room 3E-46. Telephone: (617)-681-6179 (work) or (603)-362-4297 (home).

RHODE ISLAND QSO PARTY

1700 GMT November 12 to 0500 GMT November 13
1300 GMT November 13 to 0100 GMT November 14

Sponsored by the East Bay Amateur

Wireless Association. RI stations work other RI stations and the rest of the world. All others work only RI stations. The same station may be worked twice on each band, once on phone and once on CW.

EXCHANGE:

RS(T) and state, province, country, or RI city.

FREQUENCIES:

Phone—3900, 7260, 14300, 21360, 28600, 50.110, 144.2, 146.52.

CW—1810, 3550, 3710, 7050, 7110, 14050, 21050, 21110, 28050, 28110.

Use FM simplex, no repeaters.

SCORING:

All stations score 2 points per phone QSO, 3 points per CW QSO, and 5 points for QSOs with Novices and Technicians. RI stations multiply QSO points by the number of states, provinces, and countries worked. Others multiply total QSO points by the number of different RI cities and towns worked (39 maximum).

AWARDS:

Certificates awarded to top-scoring station in each state, province, country, and RI county, plus top-scoring Novice and Technician in RI and out of state.

ENTRIES:

Logs must show date/time in GMT, call, exchange, band, and mode. Include your name, call, mailing address, club affiliation if any, total QSO points, multipliers claimed, and final score. Entries must be postmarked no later than December 15 and addressed to: East Bay Amateur Wireless Association, PO Box 392, Warren RI 02885. Include an SASE for results.

3RD ANNUAL 40-METER WORLD SSB CHAMPIONSHIP
0000Z to 2400Z
January 7, 1984

SPONSORED BY:

73: Amateur Radio's Technical Journal.

MISCELLANEOUS RULES:

Work as many stations as possible on 40-meter phone during the specified times of allowable operation. The same station may be worked *once*. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are *no less than 30 minutes each.*

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental 48 United States and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contacts with W/VE stations located within the continental 48 United States and Canada. All other contacts score 10 points each. List points for each contact on your log sheet(s).

MULTIPLIERS:

1 multiplier point is earned for each US state, 48 maximum (a District of Columbia contact may be substituted for a Maryland multiplier), each Canadian province or territory (13 maximum), and DX country (excluding the continental US and Canada).

FINAL SCORE:

Total QSO points times total multiplier points equals *claimed score.*

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Send an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1984.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each

RESULTS

YV3BRF, I5NPH, KG1E, AND N4TY: 1983 WORLD 75-METER CHAMPS

The 1983 World 75-Meter Championship is now history. The scores have been tabulated, checked, and cross-checked. There are four clear-cut winners.

In the W/VE single-operator class, it was definitely a photo finish. Only 48 points separated the first- and second-place stations. World Champion KG1E took top honors with 722 QSOs, 98 multipliers, and a total score of 83,104 points. Close on his heels with 777 QSOs, 94 multipliers, and 82,156 points was second-place finisher N5AU of Texas with K5ZD at the helm. Whowee...I wonder if each of them knew how close they were to each other in the closing hours of the contest?!

The single-operator class for DX stations was practically no contest for world-championship station YV3BRF of Venezuela. With 655 QSOs, 101 multipliers, and 132,108 total points, this station led second-place contestant IO3MAU of Italy by nearly 44,000 points.

In the W/VE multi-operator category, we had another close finish. Here again, if the two stations had known how close they were to each other, would we have seen different strategy in the closing hours? N4TY of Kentucky becomes the World Champ with 655 QSOs, 62 multipliers, and 41,106 points. Second place goes to K1WW of New Hampshire, who trailed the leader by only 1,073 points. Though the winner had 212 more contacts than his opponent, the scoring gap closed rapidly as K1WW accumulated 81 multipliers compared with only 62 for the champion. Next year, I'm sure both stations will monitor each other's activity more closely.

In DX, I5NPH and crew became the 75-Meter World Champions for DX multi-operator stations. Scoring 520 QSOs and 91 multipliers, they tallied a grand total of 101,092 points.

The following stations worked 500 or more QSOs: N5AU (777), N8II (730), KG1E (722), N4TY (655), YV3BRF (655), WB0NCR (606), KC8JH (600), KA4JNC (571), W3USS (563), IO3MAU (548), I5NPH (520), and K9EC (516).

In the contest, stations could work a total of 61 US states and Canadian provinces and territories. N5AU came the closest to the maximum with 60 worked, closely followed by YV3BRF with 59. Other stations with 50 or more W/VE multipliers included N8II (58), KC8JH (57), KG1E (57), K9EC (56), W3USS (56), KB3A (56), WB0NCR (55), N4TY (55), N1BFS (54), KI0F (54), KV0I (53), K1WW (53), HI8GB (52), N8AKY (52), WA1ZAM (52), C6ADV (51), KI7M (51), K5LZO (51), KA4JNC (50), K2GKK/5 (50), and K0UR (50).

Working DX countries on 75 meters is a challenge all its own. From the looks of the DX multipliers claimed, propagation played a big roll in the outcome of contest scoring. Naturally, European stations logged the most countries worked due to their close proximity to one another (as compared with their North American counterparts). IO3MAU had the most countries worked, with a total of 54. He was closely challenged by multi-operator champion I5NPH, who tallied 52 total DX countries. Other stations logging 25 or more included YV3BRF (42), KG1E (41), N5AU (34), W3USS (31), HI8GB (29), CT4NH (29), K1WW (28), and K8MNG (25).

Of all the contests sponsored by *73*, this 75-meter event has got to be the toughest. It has become an event participated in largely by Advanced- and Extra-class operators within the States. This, of course, is due to the band allocations and the fact that General-class licensees are extremely limited in available frequencies for contesting purposes. Adding to this dilemma is the fact that DX countries for the most part all have different parts of the spectrum in which to operate, making simplex operation rather difficult for the majority. In view of these obstacles, FCC action in the future which would further expand phone privileges for American amateurs on this band would greatly enhance the capability stations would have to maneuver. The 75-Meter Contest would see a dramatic increase of activity as a result.

With the rules changed slightly to encourage more DX participation, we expect to see even greater scores and a much larger turnout in the 1984 contest. The sunspot cycle promises to make 75 even more exciting than it has been in the past. It'll be your chance to get another "new one," so plan to attend. Obtain your forms as soon as possible by sending an SASE to Jose Castillo N4BAA, 75-Meter Contest Chairman, 1932 Highland Drive, Amelia Island FL 32034.—*Bill Gosney KE7C.*

75-METER CONTEST SOAPBOX

KA1DZV: "Enjoyed the contest—very unique!"
KG1E: "Excellent test! Propagation to all parts of the world was fantastic! Sure was a great contest."
WA1ZAM: "A great time again for the second year in a row. I'll be back."
KB3A: "Had the best of both worlds, multi-op for 40 and single op for 80."
KI3S: "Nice contest. Next year, I will plan to spend more time on the air."
W3USS: "Tremendous conditions and turnout!"
4BAA: "Wish I had had more time this year. See everyone next year for sure."
K4JPD: "I really enjoyed the contest!"
N4TY: "This was a super contest!"
W4TMR: "Can't wait until next year!"
AA6EE: "Learned that I need a better DX antenna than an inverted vee."
K8MNG: "This contest surpassed my expectations; worked 8 new countries on 75."
K9GDF: "Great contest!"
KI0F: "FB contest. Glad to be part of it. Where was Mississippi?"
JA2YKA: "Nice contest indeed. See you again next year."
VY1DV: "Too cold to stay in the shack even with the heater going. Outside temperature was 40° C. Conditions were poor, to say the least!"

TOP O'THE ROCK

NEWSLETTER OF THE MONTH

From the top of Georgia's Stone Mountain and the heart of Atlanta comes this month's newsletter contest winner, *Top O' The Rock*. Printed with pride by the Alford Memorial Radio Club, this newsletter has undergone an amazing metamorphosis in recent months.

Though once it was just another no-name newsletter, shortly after becoming *Top O' The Rock* the publication blossomed. Now it is stuffed with feature articles, news, and humor. The large number of letters to the editor received by Faye Gamer N4HLE attests to the interest club members have in their publication.

In addition to the well-designed cover, *Top O' The Rock* sports a table of contests, monthly calendar, and, of all things, advertising. Though many clubs moan and groan about the expenses of printing and distributing a newsletter, the Alford Memorial Radio Club has found a way to support its product. In addition to the supplemental income, the newsletter benefits from a dedicated staff including Alan Langford N4HUD, Production Manager; Jim Gamer KE4BI, Advertising Manager; Cary Dingler N4GPL, Circulation Manager; Reed Kreen WA3JBQ, US Post Office Liaison; and, last but not least, Big Willie GO4KILL, Master of Broken Arms.

Congratulations to Faye and her crew for an outstanding publication.

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

K8ND AND KC8JH: 1983 WORLD 160-METER CHAMPS

"Keep this line gentlemen's contest on the agenda forever"..."the contest support was overwhelming"..."it's the best 160-meter contest going!" This was the general feeling of contestants about this year's World 160-Meter Sideband Championship!

If you participated this year and are from Ohio, we don't need to tell you how devastating the competition was there. Out of the top four scores in the contest, three stations were from the state of Ohio. Between K8ND, WB8JMB, and KC8JH, a total of 2,798 contacts were made totaling 898,930 contest points. That's 160-meter contesting at its best—championship-style!

In the single-operator class, KC8JH (Ohio) accumulated 900 QSOs to become the 1983 World Champ. K8ND earned the same distinction with 1001 OSOs in the multi-operator category.

Stations achieving 500 or more single-operator contacts included KC8JH (900), AA1K (796), KØHA (710), K9QLL (663), KVØG (627), N5CG (605), N5JB (597), KC8P (591), K6SE (590), W8FGA (588), W8GIO (564), K4AQQ (560), W8UP (558), and W4TMR (532). In the multi-operator class, 500 or more contacts were earned by K8ND (1001), WB8JBM (897), W4CN (890), WA2SPL (879), N7DF (664), KBØTJ (586), and KC5DX (523).

According to contestants, propagation was truly fantastic; the majority of entries cited 40 or more W/VE multipliers worked. Many indicated they were able to earn that last-needed state or two for their WAS award.

The greatest difference noted in the scores was the amount of DX multipliers earned by competing stations. Single-operator stations working 6 or more DX countries included EA3CCN (13), N4IN (13), OK1JDX (12), AA1K (11), K6SE (9), KØHA (7), KVØG (7), K4AQQ (7), W5GFR (7), WA4SVO (7), N5CG (8), W8GIO (6), KC8JH (6), WØCM (6), and K7VIC (6). Multi-operator stations with 6 or more DX multipliers were WA2SPL (18), YU7JDE (16), K8ND (9), and WB8JBM (7).

Tabulating all the entries and cross-checking all scores revealed that more than 1300 stations were logged during this weekend event. It also appears that over 20 DX countries were represented. 1983's contest was the best ever! If you were from Alabama, Arkansas, Connecticut, Idaho, Louisiana, Minnesota, Missouri, North Dakota, or Utah, sending an entry to our contest manager would have made you an award winner from your state. Though there were many stations participating in all states, not a station from the states listed above submitted an entry. That's unfortunate. Likewise, no entries were received from Alberta, Prince Edward Island, Yukon Territory, Northwestern Territories, Labrador, or Newfoundland. With the 1984 event just around the corner, stations from these states and provinces will get a second chance to represent their areas.

Of particular interest every year is the opportunity to prove to our readers that most hams can in fact get on 160 without owning a lot of real estate. Every style of inverted vee, delta loop, and wire beam has been tried—even on small city lots! Here are some statistics extracted from contestants' entries.

160-METER ANTENNA SURVEY

	1981	*1982*	*1983*
Dipole/inverted vee	54.9%	59.6%	64.2%
1/4-wave vertical	9.1	15.8	3.8
Trap vertical	19.8	9.3	16.0
Full-/half-wave vertical	2.2	.5	1.2
Wire beam	2.1	.9	2.4
Delta loop	1.7	.9	.0
2/3-element yagi	1.4	.9	.0
1/4-wave sloper	4.4	9.3	7.4
1/2-wave sloper	4.4	2.8	5.1

Awards for the 1983 contest are being prepared at this time and should be to recipients shortly. We congratulate all the winners for their dedication to this year's effort and all the participants who made it all possible. It's been great!

As for 1984, it's promised to be the biggest year ever in 160-Meter Contest history. With the sunspot cycle in our favor, the band should be filled with new ones for the deserving DXer. Just who will be the new World Champs for 1984? Will K8ND and KC8JH retain their titles? Will former champs W9RE, W8NGO, W8LRL, or W4CN regain top honors or will it be someone from the west coast this time? Mark the dates on your calendar; the 5th annual 160-Meter World Championship is slated for January 14 and 15, 1984.

If you intend to enter this year's event, why not send for your contest entry forms today? Foreign stations especially should obtain their forms as soon as possible due to delays in mail-handling between countries. Send your SASE to: Harry Arsenault K1PLR, 160-Meter Contest Chairman, 603 Powell Avenue, Erie PA 16505.—*Bill Gosney KE7C*

160-METER CONTEST SOAPBOX

K1LPS: "Did not hear any nasty remarks or complaining in spite of very crowded conditions, although there were a few instances of deliberate jamming...something that is thankfully rare on 160."

K3MO: "Was handicapped with a sore throat. Elixia of Kentucky eased the pain."

K4IN: "The present rules discriminate against the DX station. It is much harder to work a second G or VY than another W2 in New Jersey, yet all count the same!" (Editor's note: 1984 rules will allow 5 points per W/VE contact and 10 points for all others.)

N8AKY: "Was able to work my last state for WAS! Keep this fine gentlemen's contest on the agenda forever."

W8GIO: "Could have had a couple more multipliers but refused to operate in the window."

W9LNQ: "Glad to be back on 160 after a 25-year absence. The band sounds absolutely great!"

K9QLL: "The spirit was willing but the flesh went to sleep."

dupe sheet, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Send an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1984.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each operator class in each of the continental 48 United States, Canadian provinces and territories, and each DX country represented. A minimum of 100 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or to submit an entry, contact: 75-Meter Contest, Jose A. Castillo N4BAA, 1832 Highland Drive, Amelia Island FL 32034.

5TH ANNUAL 160-METER WORLD SSB CHAMPIONSHIP 0000Z January 14, 1984 to 2400Z January 15, 1984

SPONSORED BY:

73: Amateur Radio's Technical Journal.

OBJECT:

To work as many stations as possible on 160-meter phone in a maximum of 32 hours allowable contest time. Multi-operator stations may operate the entire 48-hour contest period. Stations may be worked only once.

ENTRY CATEGORIES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental US and Canada transmit RS report and state or province/territory. All others transmit RS report and DX country.

POINTS:

5 QSO points for contact with W/VE stations contacted within the continental 48 United States and Canada. All other contacts earn 10 points each.

MULTIPLIERS:

1 multiplier point will be earned for each of the continental United States, 48 maximum (a District of Columbia contact may be substituted for a Maryland multiplier), each of the Canadian provinces/territories (13 maximum), and each DX country outside the continental 48 United States and Canada.

FINAL SCORE:

Total QSO points times total multiplier points equals *claimed score.*

CONTEST ENTRIES:

Each entry must include log sheets, dupe sheet for 100 or more contacts, a contest summary, and a multiplier check sheet.

ENTRY DEADLINE:

All entries must be postmarked no later than February 19, 1984.

DX WINDOW:

Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by top-band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band. During the contest, all W/VE stations are requested to utilize only those frequencies from 1.808-1.825 and 1.830-1.900 MHz.

DISQUALIFICATIONS:

Disqualification may result if a contestant omits any required entry form, operates in excess of legal power authorized for his/her given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which reduce the overall score more than 2%. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each entry category in each of the continental United States, each Canadian province/territory, and each DX country. A minimum of 100 QSOs must be worked to qualify.

CONTEST ADDRESS:

To obtain information or entry forms (enclose an SASE) or to submit a contest entry, contact: 160-Meter Contest, Harry Arsenault K1PLR, 603 Powell Avenue, Erie PA 16505.

itates and Canada must transmit RST and tate or province/territory. All others must ransmit RST and consecutive contact umber.

AISCELLANEOUS RULES:

The same station may be worked once on ach band. Crossmode contacts do not ount. Single operator stations may work 16 ours maximum, while multi-operator staons may operate the entire 24-hour period. Off times are *no less* than 30 minutes each nd must be noted in your log(s).

ISO POINTS:

5 OSO points for contacts with W/VE staons located within the continental United tates and Canada. 10 OSO points for all othr contacts.

IULTIPLIER POINTS:

1 multiplier point is awarded for each of e 48 continental United States (a District of olumbia contact may be substituted for a laryland multiplier), Canadian provinces/territories, and DX countries worked on each band (excluding US and Canada).

FINAL POINTS:

Total OSO points times total multipliers equals *claimed score*.

CONTEST ENTRIES:

Entries must include a *separate* log for each band, a dupe sheet, a summary sheet, a multiplier checklist, and a list of equipment used. Contestants are asked to send an SASE to the contest address for official forms.

ENTRY DEADLINE:

All entries must be postmarked no later than April 15, 1984.

DISQUALIFICATIONS:

Omission of the required entry forms, operating in excess of legal power, manipulating scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces/territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 25 OSOs must be worked to be eligible for awards.

CONTEST ADDRESS:

RTTY World Championship, c/o *The RTTY Journal*, PO Box RY, Cardiff CA 92007.

HAM HELP

I desperately need QSL information for the following stations: P29NDX, ZK2DX, SVØAT, FY7BC, 9K2EW, TF3JB, VU2TF, 5N2ØDOG, TZ4AQS, FKØBW, and 3D2DB. All of the stations were contacted during 1980.

Kenneth Ramirez WB2KQO/KP4
RR 169, Carr. 307
Cabo Rojo PR 00623

I would like to have a schematic of the Southwest Technical Products (SWTPC) 6800 System interface circuit. The unit is designated MP-L and is used to interface parallel devices with the SWTPC 6800 computer.

Now, getting back to education as a product, let's walk this through step by step so you can follow my reasoning. First, I hope you'll grant me that *73* has been educational. And perhaps you've noticed that it is fun to read. Well, that's a big key to what I have in mind. I figure that education can be made into a saleable product if it is fun. People will educate themselves if it is more fun to do that than other things. All of my computer magazines are educational and all are fun to read.

The concept of learning because it is fun instead of because one is a prisoner of the system is one which we will gradually have to get used to. I didn't like school much. I didn't like the idea of being forced to attend, whether I wanted to or not. And damned few of the courses were fun. Having enslaved students, the teachers and schools had no need to worry about whether the classes were fun. I was forced to be there by the government whether the classes were fun or not.

What was the most popular television program in England last year? If you missed all the fuss, it was Woodhouse teaching people how to train their dogs. Education—and fun. Got the idea?

Okay, now the next step. I've already written about my plans to start a high-tech college. This school is aimed at helping our country to get back into the high-tech race against Japan and will be set up as a pilot model of a new type of college, geared to the needs of the 80s. But once we have the college going, what better place to start developing the education/fun courses which we may eventually merchandise to the world?

The first step is to develop the new genre of education and put it on video tape. The next is to start selling this via an educational cable television network to get the ball rolling. Then, as video-disk technology is simpler and less costly, move to an interactive video-disk educational system which can be sold anywhere in the world in any language.

The courses should cover everything taught in grade, high, college, and graduate schools. They should go on to those courses which should be taught in school, but aren't. They should also cover business and industrial courses now being taught by businesses. They should cover all aspects of arts and crafts. Anything people may be interested in learning about should be available.

Just as we have several thousand small firms creating wealth for the entrepreneurs who are now producing software for computers, I expect we'll have thousands of small firms producing educational programs which can be distributed by larger firms, creating even more wealthy entrepreneurs.

We'll need larger firms to set up and run the distribution. That's where I think my early start with the concept may give me some leverage. In addition to having the major magazines in this new field to help it develop, I'm going to try to build IDG's present network of 42 magazines in 18 countries into an international educational distribution system.

When I think back on my time in college, I can remember one course that actually was fun. Most of them were dreadful bores, alternating memorization with written exams. Maybe it's significant that the teacher of that one exciting course eventually committed suicide. If a teacher can make accounting exciting, anything is possible.

The courses in my college will be modeled after those I took in the Navy, which were fun, and will be nothing like those I suffered in college. These will lay the groundwork for the interactive video-disk courses later on.

My recent editorials have encouraged quite a number of readers to send resumes. Obviously my plans are going to call for help from a large number of dedicated people—talented people, hard-working people. I have the ideas, know how to make them work, and have the money for it, but the end result still lies in the people I can find to make all this happen.

DX

Chod Harris VP2ML
Box 4881
Santa Rosa CA 95402

SM3CXS, who handles the QSLs for SM0AGD on his far-flung travels, met some of the DXers he has helped over the years at the Dayton Hamvention. Photo via The DXers Magazine.

THE SOUTHERNMOST AMATEUR IN THE UNITED STATES

A DXer in Hawaii has some of the best of both worlds: He's a DXer himself and has a good DX location as well. Hawaii counts as a separate "country" for DXCC, and although not hard to work, Hawaiian amateurs *are* more rare than Texas stations, for example. And Hawaii is far enough south to make it one of the best radio locations in the United States. On the southern island of the Hawaiian chain, at the southernmost tip of the island, resides Dean Paterson KH6OA.

Dean Paterson KH6OA enjoys a beautiful condominium overlooking the black sand beaches of the island of Hawaii in addition to the excellent radio propagation associated with the tropics. On the other hand, Dean feels the same restrictions as other apartment-bound hams: no outside antennas and TVI complaints. His solutions might inspire some DXers whose antennas *weren't* big enough to come down last winter.

Dean's fascination with radio began at the age of 9 with his first crystal set. However, it was 1973 before he received his first amateur-radio license. At that time, his main interest was rebuilding ARC-5 military radios. A few years later, Dean found himself moving to Hawaii into a condominium complex managed by his wife.

As is common with such projects, the sale-and-lease agreements prohibit any outside antennas. So Dean took advantage of the isolated location of the complex and the unpredictable nature of Hawaii's volcanoes and volunteered to provide emergency communications for the complex if he could have an antenna outdoors.

The owners of the condominium complex agreed to an unobtrusive vertical right outside Dean's door in the bottom corner of the complex. That proved to be enough.

Dean pounded a steel stake a couple of feet into the hard lava and attached a Hustler vertical. A few radials stretch under the vegetation, but the building blocks many of the possible radial directions. Not the best antenna system, but adequate.

To provide true emergency communications, Dean assembled a 12-volt, 2-Amp solar panel with two batteries to give 18 hours of operation. 12-volt, 2-meter rigs and low-band gear complete the emergency station.

The two-meter antenna was another problem. The main repeater on Hawaii, the one that connects into the network which serves the entire Hawaiian chain, was on the other side of the island. Dean could hit the repeater with an 11-element beam, but he couldn't get permission to erect it. He finally settled for an indoor setup. The first four elements of the beam attach to the ceiling-fan support above his head. The four elements and an 80-Watt amplifier provide a copyable signal through the massive Mauna Loa volcano.

To complete his antenna farm, Dean stretched a 60' longwire along the edge of the property to improve signals on the Big Island Emergency Nets on 40 and 80 meters. You really have to look closely to spot it, so it probably falls into the "invisible-antenna" category.

But the antenna restrictions were not the only problems in Murphy's bag of tricks. Dean soon discovered that the combination of salt spray and tropical sun dissolves antennas in months. He recently installed his third vertical in 6 years. He says his present antenna, a Butternut, is "the best vertical I've ever had, by far!"

Even that was not the end of his problems, however. Dean suffers from a common problem among apartment-dwelling hams: lack of ground. Electrical ground, that is. The hard lava of Hawaii doesn't conduct at all, and the 3" layer of top soil trucked in to grow grass is not much help. Television interference (TVI) and radio frequency interference (RFI) were, and continue to be, a serious problem.

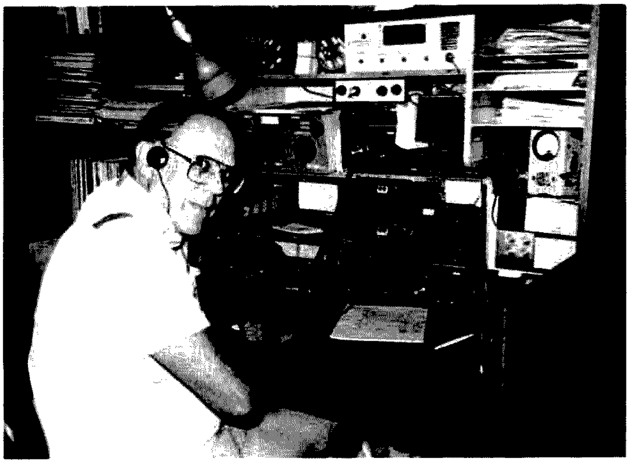
His remote location, miles from the only television transmitters on the island, means signals in the community cable-television system are marginal at best. Dean employs three Drake low-pass filters on his HF gear, and he uses toroids liberally on all power cords. But even so, he says, "If there's a football game on, I either have to go QRP or get off the air entirely."

Dean has turned this restriction into an avocation and has become a QRP enthusiast, using an Argonaut 515. He overcomes the difficult combination of apartment-style antennas and QRP power with two important advantages: his southern location and the KH6 callsign.

The low latitude means greatly enhanced radio propagation. Anyone who has operated from the tropics knows what this means: The bands open earlier in the day and close later at night. Signals from the north are much stronger than similar signals from the east or west. This tropical advantage helps to compensate for increased static and reduced grey-line communications.

And that KH6 callsign is good for a few decibels, Dean concurs. In a recent pileup on a Hong Kong station, Dean tried calling "QRP" in the pileup, without success. Then he tried "KH6" and got right through!

Dean's success with QRP shows in his results: Worked All States and Worked All Continents on QRP. He lacks only a few confirmations before earning his DXCC with 5 Watts or less.



Dean Paterson KH6OA, the southernmost amateur in the United States, operates this well-equipped station into a vertical, a longwire, and other hidden apartment-style antennas.

THE CARE AND FEEDING OF QSL MANAGERS

"Thanks for the contact, and please QSL through my manager, K1RH." How often have you received a DX QSL card through a QSL manager? These dedicated volunteers who facilitate the exchange of QSLs are the unsung heroes of the DX world. Treat them well, as they make the task of collecting DX QSLs more efficient and much less expensive.

Let's look first at how a QSL manager operates, and then we'll see what we can do to make his or her task easier to speed our return QSL.

A QSL manager serves as a go-between for the DX station and the hams who work that DX station. After an amateur works the DX station, he sends the QSL card and a self-addressed, stamped envelope (SASE) to the manager. The manager confers with the DX station, checks that the contact is in the log, and fills out and mails the DX QSL.

There are many advantages to this process over direct QSL exchange with the DX station. First, the QSL manager is usually a stateside ham, so the problems and expense of airmail overseas are greatly reduced. No matter how much you criticize the US Postal Service, they do a remarkable job, especially compared to POs in tiny, out-of-the-way DX locations. In the Galapagos Islands, for example, the mail is handed to any boat going in the right direction from the airport toward the only town. If that ship decides to change course, the mail could be delayed for months, if it ever arrives. QSL exchange with a stateside (or European or Japanese) manager eliminates this risk, is potentially faster than overseas mail, and is much less expensive.

The use of QSL managers simplifies the preparation of your own SASE. Stateside hams can usually use US postage, or, in the case of European or Japanese managers, can use a Green Stamp (US $1 bill), IRCs, or airmail stamps of that country from a DX stamp service.

So QSL managers make QSL exchange faster, cheaper, and more reliable for the DXer. QSL managers are also of benefit to the DX station. The DX station is relieved of the burden of handling volumes of mail, opening, sorting, etc., as well as the task of filling out the cards, stuffing the envelopes, and mailing. Also, the DX station's QSLs are safer in the States than in his own country. Bob YS9RVE once lost all his QSLs, including some excellent 80-meter DX, in a riot. And few DX stations want to trust several years worth of work in the form of DX QSLs to the international postage system. So when a DX station applies for an award (and they *do*, you know), the QSL manager can send in the cards, a much safer and more reliable procedure.

Are there any disadvantages to the use of a QSL manager? The major problem with QSL managers is that the logs are in one remote location and the cards are in another. Somehow the DX station must get his or her log information to the QSL manager to check the contacts. If the DX station mails the logs to the manager, you are right back to trusting the erratic Inter-

national postal system. Mail to Pitcairn Island, for example, depends on infrequent visits by yachts and cruise ships. Also, the logs can take months to reach the manager, who obviously cannot answer the QSL until he or she receives the logs.

Fortunately, there is another way the QSL manager can get the log information from the DX station: on the air. To take a typical example, let's look at how a stateside station would get a VP2ML QSL card. After the DXer works VP2ML and hears "QSL via K1RH," he fills out his QSL and puts it and an SASE in an envelope addressed to K1RH. When Ralph Hirsch K1RH receives the envelope, he opens it and sorts the contacts into date and time order, just like a logbook, until his next schedule with VP2ML.

During the on-the-air schedule, Ralph reads the date, time, and callsign. VP2ML checks his logbook and returns with the band, emission, and report, entering a checkmark in the log for "QSLed." Ralph confirms the band and emission and writes the report in pencil on the incoming QSL card. He then goes to the next card.

With practice, this procedure can be very fast. The on-the-air time to confirm the contact can be a matter of a few seconds, although Ralph still has more work after the contact with VP2ML. Ralph takes the stack of checked, incoming QSL cards and types out a stack of VP2ML cards, reading the reports from his note on the card. He then puts the blue VP2ML card into the SASE provided and drops it in the mail.

This procedure works so well that some DXers get their VP2ML cards within days of their contact. The DXer sends his card and SASE the same day as the contact with VP2ML. Ralph receives the card the next day, confirms the contact in the skad with VP2ML that night, and mails the return card later that evening. The DXer gets his VP2ML card back the next day, less than 48 hours after the contact!

Of course, all this supposes everything goes well. Reality seldom achieves this ideal. What can go wrong? The worst problem is poorly filled out incoming QSLs, especially those with bad dates and times.

VP2ML keeps his log in Coordinated Universal Time (UTC), as just about every DX station must. If the incoming QSL card has local dates and times or has miscalculated the UTC date or time, quick confirmation of the contact is impossible. VP2ML must search the log for the callsign, often over a span of several pages. If there are many other QSL cards awaiting responses, any card with incorrect information goes to the bottom of the pile for another day.

The most common date/time error is to forget to advance the day to the next UTC day during local evening operation. The next most common problem is miscalculating the time difference between UTC and local time, either adding the wrong number of hours or subtracting instead of adding.

This became so much of a problem for Ralph that he made a rubber stamp saying that he was unable to locate the contact in the VP2ML log at the date and time specified and suggesting the amateur check his QSO information again, especially the date and time.

There is really no excuse for date/time errors of this sort. Anyone interested in DX should have a clock reading UTC by the rig and keep their entire log in UTC. You can buy a tiny, stick-on digital clock for a couple of dollars. Set it to UTC and use it for all your amateur contacts. The QSL managers will love it.

Another problem which slows confirmation is multiple contacts on a single card. This card is first filed under the first contact time. But after this contact is checked, the card must be refiled into date/time order for the next contact. This increases the on-the-air time and increases the chance that interference or fading will end the schedule for that day.

Some QSL managers, including Ralph, handle cards for more than one DX station. The best way to address the envelope to the manager is to give both the DX station's call and that of the manager: VP2ML c/o K1RH QSL Manager. Then the manager can immediately sort the cards for the different stations he serves.

And finally, a short note thanking the QSL manager for his services would gladden the heart of many an under-appreciated manager. These volunteers receive nothing tangible for their efforts. They are not paid, and the few dollars which do arrive with the cards barely cover printing and postage.

So why would anyone want to handle the QSL card for a DX station? A QSL manager gets a modicum of publicity for his work, especially if he handles major DXpeditions, such as SM3CXS who handles the cards for Eric SM0AGD on his far-reaching travels. But the real satisfaction comes from the service these amateurs provide to the rest of the DX community.

Have you ever considered handling the cards for a DX station yourself? Consider these qualifications for a good manager: The QSL manager should not move around, so his or her address is good in old, new, and future callbooks. The manager should have a good enough station to maintain communication with the DX station under a variety of conditions, month after month. And the manager should be willing to work hard for remarkably little reward. Infinite patience, the ability to decipher hieroglyphic handwriting, a little ESP (for the QSL cards without date), and an understanding postman are useful but not essential additional qualifications.

Be kind to your friendly QSL manager; he or she makes your DXing a lot more pleasant.

FUN!

John Edwards KI2U

Middle Village NY 11379

SPACE COMMUNICATIONS

This is shaping up to be quite a year for amateur radio and space communications. With the launch of Phase III OSCAR and W5LFL's little DXpedition into the final frontier, future ham historians may well peg 1983 as a turning point in the development of the hobby.

I, for one, can't wait until amateur space communications really take off. At age 28, I'm still hoping to see the day when hams collect planets and space settlements the way we currently chase after new countries. Imagine heading down to your local ham club to compare QSLs from Mars, Titan, and Europa. Think of the picture possibilities on those pasteboards!

Of course, some things won't change. We'll probably still be grumbling about slow QSL bureaus, DX nets, and pileups. But like today, the excitement will be worth all the hassles. At least the weather reports should be interesting, for a change.

Let's get going and leave the rest to squabble about code/no code.

ELEMENT 1 MULTIPLE CHOICE

1) A blue whizzer is:
   1) A meteor that creates a very strong ion trail
   2) The name of a new privately-funded amateur satellite
   3) The name of Phase III OSCAR's mode A transponder
   4) A type of space antenna

2) OSCAR 6's 10-meter antennas were made out of:
   1) Tin
   2) Silver
   3) Molybdenum
   4) A disassembled pocket rule

3) Owen Garriott's son has also made quite a name for himself. He is:
   1) Also an astronaut
   2) General Manager of the ARRL
   3) A best-selling computer game designer writing under the pseudonym, "Lord British"
   4) A pro tennis player

4) On which one of the following dates did amateurs first bounce a signal off of the Moon:
   1) July 4, 1976
   2) November 21, 1954
   3) December 4, 1934
   4) January 27, 1953

5) OSCAR 1 was launched from
   1) Cape Kennedy
   2) Cape Canaveral
   3) Edwards Air Force Base
   4) Vandenberg Air Force Base

ELEMENT 2 TRUE-FALSE

	True	False
1) OSCAR 1's output was 10 Watts.	____	____
2) OSCAR 5 was built in Australia.	____	____
3) A Technician-class amateur may be a satellite trustee.	____	____
4) The Leonids meteor shower occurs in November.	____	____
5) Meteors form an ionized trail in the troposphere.	____	____
6) The first successful EME transmission used the old 5-meter band.	____	____
7) No amateur satellites were launched in 1965 through 1970.	____	____
8) OSCAR 8 travels in a north-to-south orbit.	____	____
9) One needs to run at least 1000 Watts in order to access OSCAR.	____	____
10) In ham satellite terminology, LOS stands for "linked oscillator system."	____	____

ELEMENT 3 SCRAMBLED WORDS

Unscramble these space communication terms:

REOTEM	SASBPNDA
PLOPRED	YRTTELEME
KLINWODN	ETILLEAST
DEOM	NOCABE
ELTTUHS	TRHAE
LOPRA	GINP

THE ANSWERS

Element 1:

1—1 Some have been known to reflect signals for up to two minutes.
2—4 Cheap, but practical.
3—3 No, he didn't write Space Invaders.
4—4 Ross Bateman W4AO and William Smith W3GKP did the deed.
5—4 Personally, I've always had a soft spot for ol' Edwards.

Element 2:

1—False One-tenth of a Watt. Good antenna height helps.
2—True University of Melbourne, to be precise.
3—False Extras only, according to the FCC.
4—True November 14-18.
5—False Ionosphere.
6—False It was on 2 meters.
7—True Dry spell.
8—False Depends which side of the world you're on.
9—False Hardly. 100 Watts ERP is more like it.
10—False "Loss of signal."

Element 3:
(Reading from left to right): METEOR, PASSBAND, DOPPLER, TELEMETRY, DOWNLINK, SATELLITE, MODE, BEACON, SHUTTLE, EARTH, POLAR, PING.

SCORING

Element 1:
Six points for each correct answer.
Element 2:
Three and one-half points for each correct answer.
Element 3:
Three points for each term unscrambled.

Where do you stand in the radio space race?

1-20 points—Stuck on the launch pad
21-40 points—Still listening for Sputnik
41-60 points—Confuse OSCAR signals for a band opening
61-80 points—Satellite Communicator's Club member
81+ points—OSCAR DXCC certificate holder

NEW PRODUCTS

SOFTWARE-ONLY MORSE CODE INTERFACE

Gary Woodall has announced a new concept in amateur radio and computer interfacing. Comp-Code 1.0 is a software-only Morse code interface for the Radio Shack Models I, III, and IV microcomputers.

This program uses the standard TRS-80 cassette I/O ports for input and output connections to a communications receiver and transmitter or transceiver. The results obtained from this software-only interface have been found to equal those of other hardware and software interface packages.

This 12K + machine-language program has special routines that check the incoming signal to make sure it is valid code and not noise. Bursts of noise are disregarded and only code is processed and displayed on the video screen. There also is a routine that allows you to view the incoming signal and fine-tune your receiver. The program then samples the received code and automatically adjusts to the proper speed.

The transmitter mode features five programmable buffers for a 200-character total, a type-ahead buffer, and user-selectable sending speeds up to 70 wpm.

For more information, contact *Gary Woodall Software, Box 284, Plainfield IN 46168; (317)-271-2565.* Reader Service *number 482.*

NEW DAIWA/MCM MANUAL ANTENNA TUNER

Daiwa has announced its new CNW419 manual antenna tuner featuring continuous coverage from 1.8 to 30 MHz. It is rated at 200 Watts CW, 500 Watts PEP SSB. Input impedance is 50 Ohms, with the output impedance variable from 10 to 250 Ohms.

The CNW419 also features dual antenna outputs and a switchable tuner bypass option. The tuner comes equipped with Daiwa's cross-needle meter that simultaneously shows forward power, reflected power, and swr without the sensitivity adjustments commonly found in other meters.

For more information, contact *MCM Communications, 858 E. Congress Park Dr., Centerville OH 45459; (513)-434-0031.* Reader Service number 476.

ELECTRA'S FIRST SHORTWAVE RADIO

Electra Company, marketer of Bearcat® scanner radios, has announced that it is entering the shortwave-radio market with the Bearcat DX-1000, a radio that makes dialing in the BBC comparable to dialing a push-button telephone.

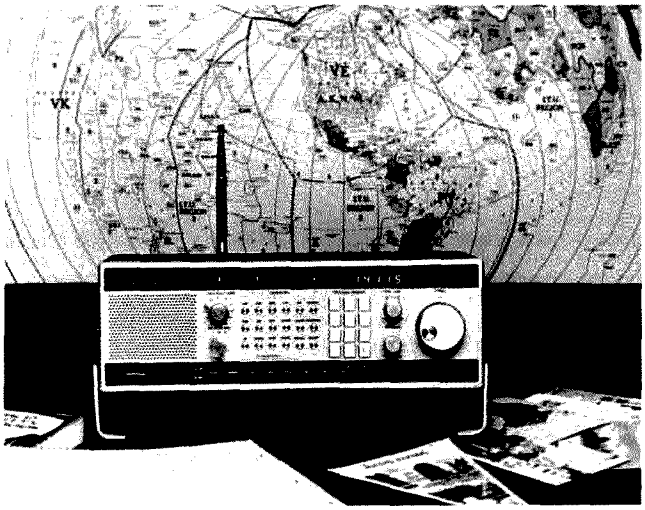
Utilizing the same microprocessor digital technology found in Bearcat scanner radios, the DX-1000 features direct-access keyboard tuning. This makes it simple to tune from the BBC (for example) to Radio Ghana without bandswitching. Covering 10 kHz to 30 MHz continuously, with PLL-synthesized accuracy, the Bearcat DX-1000 will monitor all shortwave bands, longwave, standard broadcast-band AM, amateur-radio broadcasts, and the marine band.

The DX-1000 has 10 memory channels, a digital display measuring frequencies to 1 kHz which, at the touch of a button, doubles as a two-time-zone, 24-hour digital quartz clock, and a built-in timer which can be programmed to activate peripheral equipment like a tape recorder to record up to ten broadcasts, in any frequency or mode, while the user is asleep or at work.

Other features include independent selectivity selection, with 12-, 6-, and 2.7-kHz i-f filters to help separate high-powered stations on adjacent frequencies, a two-position noise-blanking system that stops Russian pulse-radar interference, a two-position rf attenuator, FM squelch control, tone control, battery back-up system to hold memorized frequencies and time if power fails, LED indicators for modes and functions, a front-mounted speaker, fast/slow automatic gain control, and separate push-buttons for selecting AM, LSB, USB, CW, or FM modes. The unit comes with a built-in telescoping antenna for portable use and includes an SO-239 antenna connector for 50-Ohm leads and a screw-connector for "High Z."

The Bearcat DX-1000 can be operated with batteries (12 V dc) or from an electrical outlet (120/240 V ac). The unit measures 14-1/2" W × 5" H × 9-3/8" D and weighs 17 lbs. Each radio comes with a free shortwave information guide that includes listings of stations from all corners of the world.

Further details are available by contacting Electra Company, 300 East County Line Road, Cumberland IN 46229. Reader Service number 477.



Electra's new Bearcat DX-1000 shortwave radio.

WARC BANDS KIT FOR YAESU FT-101 SERIES

Fox Tango Corporation has announced a new kit which provides receive/transmit capability on all three WARC bands for all models of the FT-101 except the ZD. While only the 10-MHz band has been authorized for use to date, not much additional effort or expense is required to add all the bands while the circuit changes for 10 MHz are being made. In addition to making the old 101 ready when the new bands become available, the added capability increases the trade-in value of the set.

Based on a tried and tested design by G3LLL, the WARC bands kit is complete with all needed crystals, relay switch, and detailed instructions for moderately easy installation. For more information, contact *Fox Tango Corporation, Box 15944S, West Palm Beach FL 33416.* Reader Service number 480.

QUARTZ CRYSTAL GUIDE AND DIRECTORY

GSM, Inc., publisher of the *Quartz Crystal Industry Guide and Directory*, has announced availability of its 1983-84 edition. Companies engaged in the production of quartz-crystal products and frequency-control devices, as well as suppliers of goods and services to the industry, are listed. The directory describes the products, capabilities, and specialized services of hundreds of companies located in the United States, Canada, Europe, and Asia. Each company's key personnel, address, telephone number, TWX, and other pertinent information are detailed.

Features of this issue include expanded worldwide listings, used equipment for sale or trade, and technical publications pertinent to the industry that can be ordered from GSM.

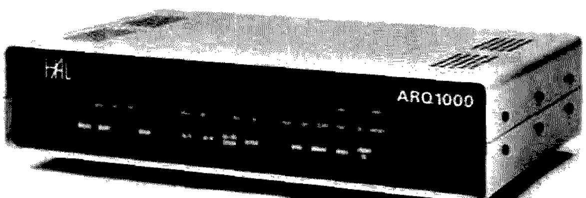
Lucille A. Hope, editor-in-chief, is now planning the *Mid-Year Update* scheduled for December. For information regarding advertising in the update or listing your company, contact the editor at *GSM, Inc., PO Box 10277, Fort Lauderdale FL 33334.* Reader Service number 481.

THE HAL ARQ1000 AMTOR TERMINAL

The ARQ1000 is a full send-receive terminal for the AMTOR ARQ code. All features of the CCIR 476-2 Recommendation are supported. Modes include: ARQ, FEC, SEL-FEC, and MONITOR. The ARQ1000 may be used with the Hal DS3100 and ST-6000, CT2200, CT2100, or CWR6850 terminals or any ASCII or Baudot terminal at baud rates from 45 to 300 baud. Non-volatile keyboard-programmable ARQ access code, selcal code, and WRU answer-back codes are included. The ARQ1000 is housed in a cabinet that matches the CT-2200 and CT2100. Available options include the DM170 internal demodulator and ARQX10 encryption module.

For further information, write *Hal Com-*

The Daiwa/MCM manual antenna tuner.



The ARQ1000 send-receive terminal from Hal Communications Corp.

munications Corp., Box 365, Urbana IL 61801. Reader Service number 479.

PHOTOVOLTAIC PANELS FROM ENCON

Encon Corporation has announced to the amateur-radio community two new photovoltaic panels, the SX-10 and the SX-20. The SX-10 is rated at 10 Watts and has different current/voltage selections, 8 V dc at 1.05 Amps and 17.3 V dc at .52 Amps, that the ham can wire himself. The SX-20 is 20 Watts, 8.6 V dc at 2.09 Amps and 17.3 V dc at 1.05 Amps.

According to Paul DeNapoli WD8AHO, Communications Director for Encon, these two new panels can be used for mobile QRP operations or mounted permanently to the roof for charging batteries.

The panels have a 30+-year life expectancy, an environmental survivability of wind loads over 160 mph and golf-ball-size hail stones, and are waterproof.

For more information, contact *Encon Corp., 27584 Schoolcraft Rd., Livonia MI 48150; (313)-261-4130.* Reader Service number 483.

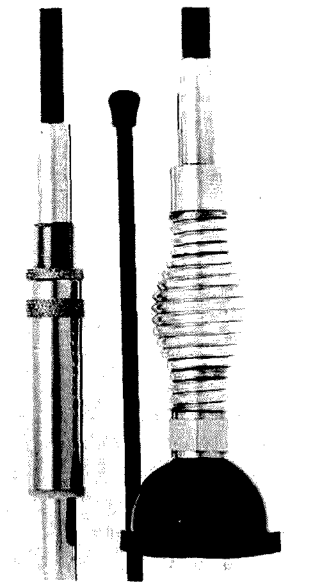
LAND MOBILE TUNABLE ANTENNAS

A land mobile antenna, available in either UHF or VHF, that's tunable over varied ranges was introduced by U. S. Fiberglass at the recent Land Mobile Expo in Denver.

The patented Stage 2 antennas utilize a voltage-fed system, differing from conventional current-fed antennas. The result is an efficient utilization of rf energy and a low angle of radiation that provides increased transmission and reception range.

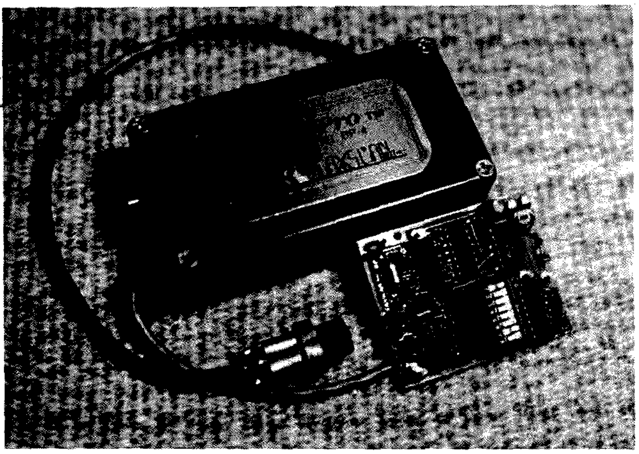
A patented reactance-canceling tuning sleeve allows the antenna to be tuned for optimum performance and then locked into position. The tuning section also allows the antenna to be tuned for a lower swr than conventional antennas.

The new antennas are suited to today's synthesized radio technology since they perform over a wide band range. They are available in eight different models, including mobile applications and base antennas.



Land mobile antennas from U. S. Fiberglass.

For further information, contact *U. S. Fiberglass, 5010 N.W. 36th Ave., Miami FL 33142; (305)-634-1115. Toll-free, nationally: 1-(800)-327-6790; Florida: 1-(800)-432-7142.* Reader Service number 478.



The Pro model BP-4 beeper from Faxscan, Inc.

THE PRO—FAXSCAN'S BP-4 BEEPER

Faxscan, Inc., has announced the introduction of their model BP-4 beeper, The Pro™. The Pro continues the concept of a "courtesy beep" to signal the beginning and end of each transmission by automatically injecting a gentle high-frequency beep into the mike line at the start of the transmission and a low one at the end. This basic idea has been used for years in commercial and military applications and NASA has used it for ground-to-space voice communications. The Pro is an upgraded version of Faxscan's model BP-3 which has been marketed to the amateur-radio community worldwide for the past three years.

The Pro adds several features not found in the BP-3. Most notable is the inclusion of a sophisticated digitally-programmable timer. The user may select timing periods from approximately 43 seconds to 10.5 minutes. Programming is accomplished by setting tiny DIP switches on the circuit board. The timer may be used as an ID timer or to warn you of impending time-out on a repeater. Time-out is noted by a unique double 4-beep sequence via a piezoelectric transducer; there is no speaker. Volume of this warning is also programmable and the warning is not transmitted.

Unlike the earlier BP-3, the beginning beep can be deleted by the setting of a switch. In this mode, a beep is added only to the end of your transmission.

Finally, The Pro incorporates a "slumber mode" to extend battery life. There is no on/off switch. Instead, the unit senses the lack of activity and shuts itself down. A single 9-V battery (not supplied) powers the unit continuously for up to a full year.

Faxscan includes a 5-page manual with The Pro, detailing theory of operation, instructions for programming the various functions, and a full-page schematic/layout along with interfacing tips. In general, The Pro will work with virtually all modern gear. Specifically, this beeper will interface directly to any rig employing a positive potential on the PTT line of less than +24 V dc and which transmits when the PTT line is pulled down to +0.7 V dc at less than 100 mA current.

The beeper comes in three versions. The A version includes a cast-aluminum enclosure, cable, and standard 4-pin mike connectors, installed. The B version is the same but without connectors. You simply add those of your choice. The C version is a circuit-board model for custom installation. For instance, the C version can be tucked inside your rig or is a perfect repeater accessory. The Pro is easily modified for most any application and the manual contains full details.

All units are fully assembled, tested, and carry a 90-day limited warranty. Faxscan ships all units postage-paid in the US.

For more information, contact *Faxscan, Inc., 3148 Dorf Drive, Dayton OH 45418; (513)-263-8475.* Reader Service number 484.

THE NEW HUSTLER TRIBAND VERTICAL

Hustler, Incorporated, has announced the addition of a new three-band vertical antenna for 10-, 15-, and 20-meter operation. A two-in-one trap design allows for excellent bandwidth while maintaining an overall height of only 12 feet.

Designated 3-BTV, the antenna is designed for permanent ground mounting with radials or for portable use on travel trailers, condo balcony railings, or wherever there is a sufficient groundplane. Construction is of high-quality aluminum with stainless-steel hardware; supplied is a heavy-duty bracket for pipe or bulkhead mounting.

For additional information on the 3-BTV or other Hustler amateur products, contact your dealer or write *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.*

KREEPIE-PEEPIE FOR AMATEUR TV

You may want to call it a handie-lookie rather than a kreepie-peepie, which was what the first cordless TV cameras were called. P. C. Electronics has come out with the KPA5, a 1-Watt UHF ATV-transmitter module board which will allow you to use any portable consumer color-TV camera.

When mounted in an aluminum box above a portable color camera, the KPA5 allows freedom to move around to catch all the action at parades, races, and other such events. If you are into videotaping you won't have to lug around a portable VCR. In fact, a standard ac-powered home VCR can be used with just an ATV downconverter ahead of the tuner set to channel 3.

DX depends a lot on antennas, terrain, etc., but up to a mile is typical under most conditions and 50 miles has been done from an airplane. For base-station use or higher-power mobile, it can be matched to the Mirage D24N amplifier for 40 Watts output. Other applications include video from R/C model airplanes, robots, computer video, weather-radar video, or practically any case where cables become too long for composite video from any source.

The KPA5 is a wired and tested board capable of full color and sound. Output is a nominal 1-Watt PEP of amplitude-modulated rf with standard 4.5-MHz sound subcarrier into 50 Ohms. It comes standard with one crystal on either 439.25 (east), 434.0 (west), or 426.25 MHz. Two channels are available with the addition of a second crystal and an external SPST switch. Inputs are: composite video from a camera, VCR, or computer, low-Z microphone, and line audio from a VCR, camera mike, or computer. Power requirement is 13.8 V dc at 280 mA. Board size is 4 × 3.25 inches.

Buyers must hold Technician-class or higher amateur licenses to operate or purchase from the manufacturer.

For more information or a complete catalog of ATV products, call or write *P. C. Electronics, 2522 Paxson Lane, Arcadia CA 91006; (213)-447-4565.*

WORKED ALL LA AWARD

The WALA Award is available to any amateur who can provide evidence of having the following requirements of the award:

Applicants in Denmark, Finland, Sweden, and Norway must have two contacts on separate bands with a total of 20 counties of Norway.

Applicants outside Scandinavia must work 20 different LA/LB stations on any amateur band. At least 6 of these stations must be located north of the Arctic Circle. Contacts with stations from JW (Svalbard), JW (Bear Island), and JX (Jan Mayen) count for this award.

All contacts must be made after January 1, 1950. Usual logbook information is required for claiming your contacts, along with the exact QTH of the station worked. Award fee is Nkr. 10, or 10 IRCs mailed to: NRRL Award Manager, Alf Almedal LA5QK, N-4052 Roeyneberg, Norway.

WORKED NORWEGIAN CITIES AWARD

This award requires applicants to work a minimum of Norwegian cities with no limit to date, band, or mode. It should be noted that this award will not recognize contacts with LJ, LF, or LH stations. The three classes are: Class 3—DX station work 5 cities, Europeans must work 10 cities; Class 2—DX station work 10 cities, Europeans must work 20 cities; Class 1—DX station work 15 cities, Europeans work 30 cities.

GCR apply. Send your completed list of contacts and application along with the award fee of 10 IRCs to: Larvik Society of NRRL, PO Box 59, N-3251 Larvik, Norway.

Valid Norwegian cities are: Alesund, Arendal, Bergen, Bodo, Drammen, Egersund, Fredrikstad, Gjovik, Halden, Hamar, Hammerfest, Harstad, Haugesund, Horten, Kongsberg, Kragero, Kristiansand S., Kristiansund N., Larvik, Lillehammer, Mandal, Mo i Rana, Molde, Mosjoen, Moss, Namsos, Narvik, Notodden, Oslo, Porsgrunn, Sandefjord, Sandnes, Sarpsborg, Skien, Stavanger, Steinkjer, Tonsberg, Tromso, Trondheim, Vardo.

From the Vadso Society of the Norwegian Radio Relay League come details about the worked all "communes" award for this Scandinavian country.

WORKED ALL NORWEGIAN COMMUNES AWARD

Licensed amateurs and SWLs worldwide are encouraged to pursue the requirements of this very challenging awards program. This award is issued for contact with 25 different Norwegian communes; an endorsement sticker recognizes each additional group of 25 communes. At present there are over 454 communes and 5 Norwegian arctic/antarctic areas which qualify for contacts. A special award will be issued to those who can work all communes and all arctic/antarctic areas. Only contacts on or after January 1, 1975, will count for WANCA.

All bands or modes may be used; no crossmode contacts or contacts via repeater will be allowed for credit. QSOs via OSCAR satellites do count. Minimum reports in all cases must be RST 338 or RS 33. Mobile or portable contacts count, but QTH must be stated on the QSL card.

QSL cards are not required. GCR apply. Award fee is Nkr. 30 for the basic award (10 IRCs) and Nkr. 10 (3 IRCs) for endorsement stickers. No fee for handicapped amateurs/SWL stations.

A record book listing all Norwegian communes and areas is available from the Award Manager for 15 Nkr. (3 IRCs).

Certificates are issued for mixed mode, CW only, SSB only, all RTTY, all SSTV, Novice, mobility (only contacts with mobile or portables), and All WANCA.

All fees are contributed to the LA5LG Fund for Norwegian Blind-Handicapped Amateurs. All inquiries should be accompanied with at least 2 IRCs for an expected reply.

All applications should be forwarded with the appropriate fee to: WANCA Award Manager, Sverre J. Schmidt LA1QK, PO Box 3, N-9801 Vadso, Norway.

DX AWARDS FROM NEW ZEALAND

I just received a very informative packet of information from NZART, the national amateur society of New Zealand. Jock White ZL2GX, as awards manager, indicates that all NZART awards are available for a nominal fee and QSL cards are not required where verified lists can be provided as an alternative. To qualify, all contacts claimed for NZART awards must be made on or after November 1, 1945. Special endorsements are given for single-band or -mode accomplishments. Send all applications to ZL2GX, 152 Lytton Rd., Gisborne, New Zealand.

Worked All Pacific Award

To qualify for the WAP Award, an applicant must confirm two-way contacts with 30 different Oceanic countries from the WAP list below. The cost of this award is 2 IRCs or US $.60.

Eligible Oceanic contacts: Port Timor, Philippines, Adelie Land, New Caledonia, French Oceania, Wallis Island, New Hebrides Baker/Howland/American Phoenix Islands, East Carolines, West Carolines, Mariana Islands, Marcus Island (Minami Torishima), Guam, Hawaiian Islands, Johnston Island, Midway Island, Palmyra, American Samoa, Wake Island, Marshall Island, Java, Sumatra, Borneo, Celebes, West Irian, Australia, Lord Howe Island, Willis Island, Macquarie Island, New Guinea, Norfolk Island, Papua, Nauru, Christmas, Cocos, Gilbert, Ellice, British Phoenix Islands, Fiji, Fanning and Washington Islands, Solomon Island, Tonga, Pitcairn, Sarawak, Brunei, North Borneo, North Cook Islands, South Cook Islands, Samoa, Tokelau Islands, Kermadec Islands, Niue Island, New Zealand, Chatham Island, Auckland and Campbell Island, Antarctica (ZL5 only).

New Zealand Award

The NZA is available to all radio amateurs other than ZL. A total of 101 contacts is required to qualify for this award. All contacts must be made after December 8, 1945.

Applicants must make the following contacts: 35 ZL1 contacts, 35 ZL2 contacts, 20 ZL3 contacts, and 10 ZL4 contacts, plus 1 contact with a ZL "territory" (either New Zealand, Antarctica, Chatham Island, or Campbell Island). This one contact may be substituted by 20 additional ZL contacts not already claimed.

Worked All New Zealand Award

The WAZL Award requires that contact be made with 45 different branches of NZART—except for overseas applicants, for whom only 35 contacts are required.

A special endorsement is given if the WAZL Award is accomplished within a 12-month period. Mobiles operating outside their regular branch area must sign the branch from which they are mobile while operating. Endorsements are also given for single-band or -mode operations. All contacts must be made after November 1, 1945, to qualify.

NZART branches are as follows: 01 Ashburton, 02 Auckland, 03 Western Suburbs, 04 Cambridge, 05 Christchurch, 06 Dannevirke, 07 Blank, 08 East Southland, 09 Egmont, 10 Franklin, 11 Gisborne, 12 Hamilton, 13 Hastings, 14 Hawera, 15 Hawke's Bay Central, 16 Horowhenua, 17 Huntly, 18 Hutt Valley, 19 Inglewood, 20 Manawatu, 21 Manukau, 22 Marlborough, 23 Marton, 24 Motueka, 25 Napier, 26 Nelson, 27 New Plymouth, 28 Northland, 29 North Shore, 30 Otago, 31 Pahiatua, 32 Rahotu Coastal, 33 Rotorua, 34 South Canterbury, 35 South Otago, 36 South Westland, 37 Southland, 38 Taumarunui, 39 Tauranga, 40 Te Awamutu, 41 Thames Valley, 42 Tita-hi Bay, 43 Waihi, 44 Matamata Radio Club, 45 Waimarino, 46 Wairarapa, 47 Waitara, 48 Wanganui, 49 Westland, 50 Wellington, 51 Eastern Bay of Plenty, 52 Wairoa, 53 Te Puke, 54 Patea, 55 Waitomo, 56 Hornby, 57 Tokoroa, 58 Helenville, 59 Mangakino, 60 Taupo, 61 Central Otago, 62 Reefton Buller, 63 Upper Hutt, 64 North Otago, 65 Papakura, 66 Auckland VHF, 67 Kawerau, 68 North Canterbury, 69 Kapiti, 70 Fielding, 71 Rodney, 72 Opotiki, 73 Hobson, 74 Western VHF.

New Zealand Counties Award

The Basic NZC Award requires contacts with 20 different New Zealand counties. Endorsements are made for 40, 60, 80, and 100 contacts, with a special certificate for 112. A map showing the counties is available by writing NZART (ZL2GX) directly. Enclose 10 cents or 1 IRC to cover handling.

The initial award with any or all endorsements costs 45 cents or 3 IRCs. Separate endorsements thereafter cost 10 cents or 1 IRC. The special NZC 112 Award costs 45 cents.

Contacts may be made single band or any mode to qualify. GCR apply. Applicants must provide a list of contacts detailing the usual logbook data.

5 × 5 Award

This premier award has been instituted to recognize the increasing interest in 5-band DX operation. The initial award requires that the same station be contacted on 5 bands repeated with 5 different countries.

A certified list with full QSO data and fee of $1.00 is required. The certificate is outstanding and is overprinted in embossed gold. Contacts must date from 1945.

ZLA Award

To qualify for this award, applicants must contact Auckland City ZL1, Wellington City ZL2, Christchurch City ZL3, Dunedin City ZL4, Antarctica ZL5, Campbell Island, Chatham Island, and Kermadec Island. There are endorsements given for single band or mode.

Award fee is 45 cents or 3 IRCs. GCR apply.

Individual ZL District Awards

All ZL district awards are 35 cents each or 3 IRCs. Later endorsements are accessed at 10 cents or 1 IRC apiece. All contacts must be dated post war.

ZL1 Award—Contact 125 different ZL1 stations. Endorsements are recognized for 175 and 250 contacts.

ZL2 Award—Basic award requires contact with 100 different ZL2 stations, with endorsements given for 150 and 200.

ZL3 Award—Basic award requires 50 ZL3 contacts, and endorsements are given applicants claiming 75 and 100.

ZL4 Award—This award requires only 25 ZL4s be worked, with endorsements given for 35 and 50.

Captain James Cook Award

The CJC award, as it is called, perpetuates the memory of this world famous navigator and seaman—in three classes. 1. The basic "Sailor" class requires contacts with G in Yorkshire, FO8, ZL2, VK2, and KH6. 2. For "Officer" class, applicant must first possess all the Sailor-class contacts plus ZL1, ZL3, ZL4, VK3, VK4, VK9 New Guinea, and any Antarctica station. 3. For "Command" class, both the previous classes must be earned plus five of the following: VE2, VO, A35, YJ8, FK8, CE0, and KL7.

Cost of this award is 45 cents in stamps or IRCs. GCR apply.

YL ZL Award

The Women Amateur Radio Operator Award (WARO) requires VK and ZL stations to work at least 12 members of the WARO. DX stations must work at least 5 members. All contacts must be made after June 1, 1969, and must include one each from ZL1, 2, 3, and ZL4.

Net contacts do not qualify. There are no band or mode limitations; however, all contacts must be made from the same QTH for all.

Unlike all the previous awards shown so far, send your list of contacts along with your QSL cards to the Award Custodian, Thelma Souper ZL2LO, 62 Kirk Street, Otaki, New Zealand.

There was no mention of an award fee, but to be safe and courteous, it is advisable to enclose at least an amount for sufficient postage to return your cards.

In the event you missed the address for all applicants for NZART awards, please forward your requests to Mr. Jock White ZL2GX, 152 Lytton Road, Gisborne, New Zealand. Be sure to tell Jock you heard about the NZART awards from *73* magazine.

CANADIAN AWARDS FROM CARF

The Canadian Amateur Radio Federation (CARF), Inc., is pleased to announce the following radio-amateur awards available to operators worldwide.

Canadaward

A colorful certificate will be issued to any amateur who confirms two-way contact with all Canadian provinces and territories. Awards will be issued for any band, six to 160 meters, and any mode via OSCAR satellite. Modes may be mixed, CW, SSB, RTTY, SSTV, or any other authorized emission.

All contacts must be made after July 1, 1977. To qualify, applicants must forward QSL cards with $2.00 or 10 IRCs plus sufficient funds for the safe return of your

cards. CARF members need only submit sufficient funds for returning QSLs. Mail your fee, application, and QSLs to: Canadawards, PO Box 78752, Vancouver BC, Canada V5R 5S7.

List of Canadian provinces and territories which qualify for this award: VO1/VO2 Newfoundland and Labrador, VE1 Prince Edward Island, VE1 Nova Scotia, VE1 New Brunswick, VE2 Quebec, VE3 Ontario, VE4 Manitoba, VE5 Saskatchewan, VE6 Alberta, VE7 British Columbia, VE8 Yukon Territory, VE8 Northwest Territories. Note: VO1 or VO2 count as one required contact.

5-Band Canadaward

A special plaque will be issued to any amateur who confirms two-way contact with all Canadian provinces and territories on each of five separate bands (12 cards per band for a total of 60 cards). All contacts must be made after July 1, 1977. Submit the 60 cards with $10.00 or 70 IRCs plus sufficient postage for the safe return of your QSLs. Should you work 6 or 7 bands using the same Canadaward criteria, special endorsements will be provided upon proof of your claim. As with the basic Canadaward, forward your applications to PO Box 76752, Vancouver BC, Canada V5R 5S7.

NIAGARA FALLS

The Niagara Falls Radio Club, Inc., will operate a special-event station during the Festival of Lights, from Niagara Falls, New York, seventh wonder of the world. The Festival of Lights is one of New York's top ten winter attractions. The callsign will be W2QYV. Dates are November 26th through January 8th; time will be from 1500 UTC to 0300 UTC. All contacts will be in the General portion of 20, 40, and 80. To apply for this award, send QSL card and $2.00 donation, along with an SASE (8½ by 11) with $.55 postage for the color photograph award, to: Awards Manager, Angelo Zino WA2UJR, 16 Council St., Niagara Falls NY 14304.

CW GROUP OF RIO DE JANEIRO CWRJ AWARDS PROGRAM

Important Notes: LOG-GCR apply. 1. All awards CW only, 2-way, or SWL. All bands mixed unless otherwise noted. 2. A single CWRJ Operator Team Member may be used for more than one CWRJ award, but only if worked on other bands, or on a different date. 3. CWRJ Associate Membership is available to foreign amateurs, see: WAMAW Award, below. 4. Endorsement seal fee: none, send an SAE and 1 IRC for surface mail.

CWRJ Operator Team Members (Oct. 82): PY1s: AFA, AFG, AJK, ASI, BFZ, BGI, BMF, BOA, BQQ, BUG, BUL, BVY, CBW, CC, CCX, CCY, DCG, DEA, DFF, DGB, DIN, DJY, DN, DPG, DUB, DUH, DWM, EBK, EWN, FB, HQ, LG, MHQ, MKA, RJ, TCJ, UET, URQ, VB, VEC, VKA, VLR, VMV, VOY, WDS, WO.

CWRJ Award: CWRJ

CW only. Work 20 different PY1 stations including 5 members of the CWRJ Operator Team. Endorsements: 6, total. Each 5 new PY1 stations, including 1 new Operator Team Member.

Log: complete. Fee: 6 IRCs. Valid: after Dec. 16, 1980. Manager: PY1EWN, PO Box 621, 24000 Niteroi, RJ, Brazil.

Brazilian Stations Award: BSAW

Work 75 Brazilian stations including 10 Federation Units (states/territories) and 2 CWRJ Operator Team Members. CW only. Each state/terr. has different prefix: PY1, PT2. Endorsements: 2. First: 50 additional Brazilian stations. Second: 25 additional Brazilian stations.

Log: call/date. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Manager: PY1EWN, PO Box 621, 24000 Niteroi, RJ, Brazil.

Rio De Janeiro State Cities Award: RJCAW

Work 10 cities of Rio de Janeiro State (RJ)—PY1—including 2 CWRJ Operator Team Members. CW only. Endorsements: none (on initial application, any award will be endorsed QRP upon request and proof).

Log: call/date/cities. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Manager: PY1DWM, PO Box 24039, 20522 Rio de Janeiro, RJ, Brazil.

Diploma Brasil Geografico: BGAW

Work 3 stations of each geographical region of Brazil, 15 total contacts, including 1 S.E. region CWRJ Operator Team Member. Endorsements: none (on initial application, any award will be endorsed QRP upon request and proof). CW only.

Geographic regions: Norte (NO-North): PP8, PT8, PU8, PV8, PW8, PY8. Nordeste (NE-Northeast): PP6, PP7, PR7, PR8, PS7, PS8, PT7, PY6, PY7. Sudeste (SE-Southeast): PP1, PY1, PY2, PY4. Sul (SU-South): PY3, PP5, PY5. Centro Oeste (CO-Midwest): PP2, PT2, PT9, PY9.

Log: call/date. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Manager: PY1DFF, PO Box 1045, 24000 Niteroi, RJ, Brazil.

Worked CWRJ Associate Members Award: WAMAW

CW only. Work 10 CWRJ Associate Members and/or CWRJ Operator Team Members. Endorsements: 2. First: 5 additional CWRJ Associate Members. Second: same.

Log: call/date. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Manager: PY1EWN, PO Box 621, 24000 Niteroi, RJ, Brazil. Note: CWRJ Associate Membership is available to foreign amateurs with a profound interest in Brazilian CW Groups' activities, awards, etc. SASE to W5XW for details in English; PY1EWN in Portuguese; DJ3WM in German.

Brazil's Frontiers Award: BFAW

CW only. Work 5 countries which have frontiers (borders) with Brazil: (FY, PZ, 8R, YV, HK, OA, CP, ZP, LU, CX).

Log: call/date. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Endorsements: none (on initial application, any award will be endorsed QRP upon request and proof). Manager: PY1DFF, PO Box 1045, 24000 Niteroi, RJ, Brazil.

CWRJ "YL" Flowers Award: YLAW

CW only. With the first letter of the suffix of the callsigns of stations worked in the 10-meter (28-MHz) band, spell the names of 5 (five) flowers (English or Portuguese names); stations worked must include 5 (five) YL operators. YL stations may be used to substitute letters in the names of flowers (as in poker: wild cards); YL contacts may be on any band. Contacts may be any country. Endorsements: none (on initial application, any award will be endorsed QRP upon request and proof).

Log: call (listed in order to form names of flowers)/YL info/date. Fee: 6 IRCs. Valid: after Jan. 1, 1982. Manager: PY1DWM, PO Box 24039, 20522 Rio de Janeiro, RJ, Brazil.

Worked CWRJ Awards: WRJA

CW only. Applicants must have the basic CWRJ Award plus 5 others from the CWRJ Award Program. Endorsements: none (on initial application, any award will be endorsed QRP upon request and proof).

Log: numbers/names of awards. Fee: 6 IRCs. Manager: PY1DFF, PO Box 1045, Niteroi, RJ, Brazil.

GAITHERSBURG MD

The NBS-BRASS will operate K3AA November 3 through November 6, 1983, in observance of the dedication of the first active amateur-radio club station at the National Bureau of Standards. Multi-op activities on CW, phone, and RTTY will be near the low end of the 80- to 10-meter Novice- and General-class bands. Certificates can be obtained by sending an SASE to BRASS, c/o National Bureau of Standards, Mailroom, Washington DC 20234.

CHESAPEAKE APPRECIATION DAYS

The Anne Arundel Radio Club will operate W3VPR from Sandy Point State Park, near Annapolis, Maryland, as part of the annual Chesapeake Appreciation Days celebration, October 29 and 30, 1983. Operation will be from 1000 until 1600 EDT in the lower part of the General-class CW and phone bands, 40 and 20 meters, and CW in the 15-meter Novice band. Certificate via PO Box 604, Glen Burnie MD 21061.

SPECIAL-EVENT STATION WA2UEC

Rocky Point, New York: The Radio Central Amateur Radio Club will operate WA2UEC from the former RCA High-Frequency Radio Station, called "Radio Central," on Saturday, November 5, and Sunday, November 6, to commemorate the 62nd year of the station (now silent), part of the New York State Park. Operations for the 24-hour period will be on 2-160 meters, up 10 kHz from the edge of the General band, and on two meters on these frequencies: 146.52, and 144.550/145.150 repeat. Novice-band operation will be on 7.110 kHz.

A special QSL card showing a photo of the former station will be available. Send your QSL with a large SASE to Radio Central Amateur Radio Club, PO Box 680, Miller Place NY 11764, or QSL to the *Callbook* address.

MICHIGAN AMATEUR RADIO LADY OF THE YEAR

The recipient of the 1982 Michigan Amateur Radio Lady of the Year Award was Aileen Gagnon WA8DHB of Gladstone, Michigan.

Aileen has been a very active member of the amateur-radio community since she was first licensed in April of 1962. Her particular area of interest is public-service communications and she is highly involved in various aspects of the national traffic system. Aileen is an assistant section manager (for Michigan's upper peninsula), official relay station, net manager of the upper peninsula net, member of the TASYL, UPYL, MACS and MITN Michigan Nets, a net control for the MITN, and is active on the MATW (Michigan amateur traffic workshop). She also is very active in emergency communications and is net control for the upper peninsula ARES net as well as prime organizer for net activities during the SET.

Aileen has received two certificates of

merit from the ARRL and is a past president of her local radio club, the Delta County Amateur Radio Society, and a member of the local repeater association.

During her very rare spare moments, Aileen keeps a constantly updated card file of all the upper peninsula hams. This is used to print an annual UP ham directory.

Aileen is a busy housewife (hubby is Melvin), and she has a son, a daughter, two stepdaughters, a stepson, and six grandchildren. Also, Aileen and Mel have one of the truly outstanding vegetable gardens in Delta County.

The Michigan Amateur Radio Lady of the Year Award is presented each year at the ARRL state convention in Muskegon, Michigan, by the section manager.

WORKED ALL "QST" AWARD

If you like to collect awards, here is a new one for you. The Worked ALL "QST" Award, sponsored by the CRRL.

As most of you might already know, the "QST" suffix has been assigned to the CRRL in all Canadian call areas. VE_QST calls are used by official bulletin stations across the country. These stations are active during League contests and public-service events. They also provide regular bulletin services to local nets and on a nationwide basis to Canadian hams.

This Worked ALL "QST" Award is available in five categories: CW, phone, RTTY, mixed, and QRP, with four endorsements: VE0, VO2, VE8, and VY1.

To qualify, one must work all eight stations from VO1, VE1 through VE7. Once you have all eight "QST" QSL cards, you can send them to CRRL, Box 7009, Station E, London, Ontario, Canada N5Y 4J9, or directly to the award manager, John Gowron VE4ADS.

The licensees who control the use of "QST" calls and maintain logbooks for QSL purposes are: William Kremer VE7CSD (VE7QST), Bill Gillespie VE6ABC (VE6QST), William Munday VE5WM (VE5QST), Peter Guenther VE4PG (VE4QST), Dick Reiber VE3IBV (VE3QST), Don Welling VE1WF (VE1QST), and Clarence Mitchell VO1AW (VO1QST).

The four endorsement calls will be active from time to time. Watch these pages for announcements.

LETTERS

COMPU-KIDS

Just a note of appreciation regarding *73*. I find it informative, timely, accurate, and comprehensive. I read your editorials with an open mind and feel you do have a progressive attitude. I don't always agree, however. For example: The young fellows I have Elmered had no difficulty with the code but really can't cope with the written. Part of the problem, of course, is the lack of study-habit training in our school systems. However, I agree that amateur growth is the primary necessity.

The VIC-20 code program in the August, 1983, issue is what prompted me to write. This is an excellent little program and it works. This approach should help lots of computer kids get started. I had my nephew type it in and after a few corrections (his mistakes) it ran nicely. I am going to rework it to run on my TI99/4A and will send it in if somebody doesn't beat me.

I, too, am an ex-submariner, Wayne. I served as a Torpedoman on the *Puffer*, *Moray*, *Boarfish*, and *S-12* (training). A great experience!

Well, I'd better get back to learning how to use my new word-processing program so that I can retire this turkey typewriter.

J. W. Guthrie KF6FC
Cermel CA

JW, the more I get involved with my college project, the more I understand how much change is needed in our schools. We need to stop thinking of them as public baby-sitting systems and start teaching 'em things again. I can't believe how much lower grade education has changed since I went to school fifty years ago.—Wayne.

CW CLUTTER

I have been following your editorials about the elimination of code requirements for a ham license. For over 25 years, I was involved in non-communication electronics. My work involved design, prototype construction, and supervision of technicians.

For over 50 years (since I was about 15), I have wanted to become a ham, but I have refused to clutter my mind with code just to pass some test. I have never had any interest in CW communication and once the test was passed I would never use the code again. As the result of my conviction, I have never had a license.

Keep trying, but I don't think we will live long enough to see the day when "Reason rules the day."

I like *73* very much and find the construction articles very good. Keep up the good work.

James C. Anderson
Albuquerque NM

BUY AMERICAN?

It is truly amazing the powers encompassed in the printed word. Your excellent reporting of the contents of Joe Vegh's (W5VSV) letter regarding his attitude about buying American was thought-provoking and meaningful. What a powerful statement was made when he stated he would "straighten screws, glue on decals, touch up paint, and complain like hell before buying foreign products." The only thing I ever did was "complain like hell" because it did not occur to me to do the other things mentioned. The domestic products I have purchased recently seem to need more than screws straightened or decals re-glued. Hell fire, I have some items total rebuilding cannot cure. When I raise hell with the manufacturer, all I get in return are nasty letters or excuses such as: "The union members do not do their job" or "American workers cannot do a dollar's worth of work for a dollar anymore; they have to have $5.00 and two men to do one man's job." I wonder if Joe gets better results raising hell than I get.

I, too, suffered at the hands of our Nipponese friends in World War II. During their attack on Pearl Harbor, December 7, 1941, my ship (*U.S.S. Utah*) went down so fast many of my friends failed to swim to safety, so I, too, can see where Joe can conjure up ill will toward the Japanese. My father nearly had a stroke in 1974 when I drove up in a brand new Toyota. No amount of explaining could ever convince him my reasoning was sound. "But the car is built better than modern American cars," "But, Dad, my time can be better spent than straightening screws or re-gluing decals and touching up paint," "But, Dad, this car actually runs for days on end without benefit ot a push or pull from outside sources."

All of this fell on deaf ears because my father did what Joe advocates: Buy no foreign products . . . unless you need them or want them. My father did not use Joe's disclaimer, however. He did not buy foreign! Not to his knowledge, anyway. When I pointed out his clock radio was made in Taiwan, his color television was 96% Japanese made, his car radio (in his 100% American-made car) was a Japanese product, and several other items in his household were also foreign, his second near-stroke of the day was not long in coming.

After reading your editorial on the subject, my wife and I decided to re-evaluate our position and become 100% American in our daily purchases. After all, I used to give talks about "Americanism" at local high schools and service clubs. What a traitor! Talking about being loyal on one hand and then going out availing myself of foreign products. So we came up with ideas we think everyone should follow.

No more Italian sausage, French wine, German beer, Swedish meatballs, Russian vodka, caviar (unless the sturgeon checks out to be born and raised in American waters), Spanish rice, Hungarian goulash, French, Italian, and Vienna bread, Chinese noodles, borscht, Irish stew, Soul Food (didn't we import those people from Africa?), Danish rolls, Sukiyaki, Chinese egg rolls, Spanish omelets, spaghetti, Irish potatoes, and many, many other things. For a complete list, don't send me a letter. Just forget it. My wife and I are contemplating losing a lot of weight.

Then we got into wearing apparel. We came to the conclusion that naked is as naked does. There isn't much available that is not made in its entirety or assembled in foreign manufacturing plants. This is going to be tougher than we thought.

Our final conclusion was to buy clothes and food from the only true American extant, the American Indian. There is, however, a rumor that even these people sneaked into the United States via some land bridge between Russia and Alaska. Can anyone confirm or deny this? If this cannot be solved, we simply do not know what we are going to do for survival. By the way, can anyone inform me whether or not the Indians make automobiles and television sets? Radios? Lawn mowers? Computers? I know they make rugs and jewelry, but I don't think I would look good wearing a formal rug, jewelry, and nothing else.

Joe could have refrained from writing and you, Wayne, could have let well enough alone and *not* commented on it. As it now stands, we (my wife and I) can't find too much to eat, enough clothing, automobiles that don't break down the day after warranties expire, products that don't need screws straightened and decals glued back on, and worst of all—how about that ham I just heard calling CQ? He had a terrible accent and a foreign call! Do I dare invite him into our country by answering his call?

Wayne, you and Joe are troublemakers. Why didn't both of you just keep still so I could go on buying products on merit and not because it was made here or there? All this time I thought I was a discerning purchaser picking and choosing that which worked best for me, and now you two come along and shatter my whole style of living. I'm thinking of giving up on *73* as I heard a rumor your stapling process for the magazine is of dubious parentage. Shucks!

Jim Oberto WA9YYV/7
Phoenix AZ

P.S. Was the /7 needed? I am confused now.—J.O.

BOOTLEGGER!

For the past six months, we have been receiving QSL cards for contacts made with EL7M. All attempts on our part to pinpoint the location of this illegal operator have failed.

Please be advised that the callsign EL7M is not a legally issued callsign by the Ministry of Post and Telecommunications, Republic of Liberia. The user of this callsign is therefore a bootlegger.

It would be appreciated if all legally licensed ham operators would assist us in trying to identify this individual and pass the word around of this illegal operation.

Please note that all QSL cards received by the EL Bureau for contacts made with EL7M will be discarded.

H. Walcott Benjamin EL2BA, President
Liberia Radio Amateur Association
Monrovia, Liberia

Sonofagun, you mean that two-meter contact with EL2M was a pirate? Damn!—Wayne.

TO THE HILT

The first thing I read when I get my *73* is your editorial and I always enjoy it to the hilt. If I ever have the chance to meet you face to face, I would like to shake your hand—I've always been an outspoken person myself.

As a new ham—a Novice at the age of 56—I got started late and sure wished I had known about amateur radio 30 years ago. I am now working with my wife and 14-year-old grandson on code.

Keep the good work up—we need more people like you to speak out.

Gene Smith KA6ZAH
Oroville CA

A pox on the hams of Oroville for managing to keep amateur radio a secret from you all those years. I sure hope you won't carry on in the Oroville tradition. Get out to the high school and get a ham club started, using your grandson as bait.—Wayne.

THE SELECTRIC™ INTERFACE

Daisy wheel quality without daisy wheel expense.

You need the quality print that a daisy wheel printer provides but the thought of buying one makes your wallet wilt. *The Selectric™ Interface*, a step-by-step guide to interfacing an IBM Selectric I/O Writer to your microcomputer, will give you that quality at a fraction of the price. George Young, co-author of *Microcomputing* magazine's popular "Kilobaud Klassroom" series, offers a low-cost alternative to buying a daisy wheel printer.

The Selectric™ Interface includes:

- step-by-step instructions
- tips on purchasing a used Selectric™
- information on various Selectric™ models, including the 2740, 2980, and Dura 1041
- driver software for Z80, 8080, and 6502 chips
- tips on interfacing techniques

With *The Selectric Interface* and some background in electronics, you can have a high-quality, low-cost, letter-quality printer. Petals not included.

Credit card orders call TOLL-FREE 1-800-258-5473. Or mail your order with payment plus $1.50 shipping and handling to: Wayne Green Inc. Attn: Retail Book Sales, Peterborough, NH 03458.

73 INTERNATIONAL

from page 82

the 60-year mark this year. They are M. W. Coutts of Auckland and W. M. (Soupy) Groves W5NW, whose original US call in 1923 was U5NW, according to the OTC Directory.

Arthur (Jumbo) Godfrey ZL1HV, retiring president of NZART, was made a Life Member of the Association at the Annual Conference at Dunedin. Jumbo was also recently appointed a Director of IARU Region III Association in the place of Tom Clarkson ZL2AZ, who retired from the position.

Honors: Tom Clarkson ZL2AZ was honored by Her Majesty Queen Elizabeth in her New Zealand Birthday Honors List, being awarded the medal of Ordinary Member of the Order of the British Empire (M.B.E.) for his services to amateur radio. Tom has had a long association with ham radio since he was first licensed in 1925; he has been NZART President, an NZART Councillor, a foundation Director of IARU Region III Association, and a Life Member of NZART. The recognition by the Queen in her Birthday Honors is well deserved.

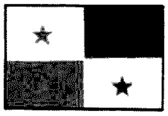
Changes to amateur-radio frequency allocations in ZL from August 1, 1983, have been issued by the regulatory body, the New Zealand Post Office. The main changes are the extension of Grade II licenses and Novice licenses and an extension of the 160-meter band.

Grade II licensees may now operate the 10-meter band between 28 MHz and 29.70 MHz, as well as the other bands previously allocated. The Novice operators have also been allocated a segment of the 10-meter band between 28.10 and 28.60 MHz. The extension of the 160-meter band, which now covers 1800 to 1959 kHz, will be of benefit to Grade I and Grade II operators.

Another change introduced by the NZ Post Office has been the deletion of the Modes of Emission from the Frequency Allocation List. They have placed the responsibility on NZART to set the band plans for each band, based on IARU recommendations, and on all of us to ensure that the mode of emission employed is compatible with other band users and that the bandwidth of the emission is not excessive and does not interfere with others. The NZART Frequency Management Working Group has produced a draft proposal for the New Zealand band plan which is in line with the modes of emission that are in use now (the time of writing this is July), and basically there are no changes, just a shift of responsibility in the allocation and implementation of the modes of emission.

The new 18-MHz and 24-MHz bands are still in the pipeline, but there has been a small change in the 10-MHz band. It is now open from 10.10 to 10.15 MHz for Grade I operators only.

There are many alterations in the VHF and UHF bands; nine new bands are being added above 47 GHz as well as many new segments for the Amateur Satellite Service, which corrects the near-tragic outcome of the 1971 WARC Space Conference when meager provision was made for the Amateur Satellite Service. Provision has also been made for the use of certain bands for international traffic at a time of natural disaster. This is a new provision for many countries as a result of WARC-79 Resolution 640, but it is an amateur-radio function that NZART has always supported.



PANAMA

Miss Dayra Z. Chang HP1AZC
Apartado 6-1175
El Dorado
Panama, Panama

From L. O. Mathieu HP1ALX: Any radio amateur who visits the city of Panama would be very happy with the courtesy and the friendly treatment that radio amateurs offer in this country.

It can be a great surprise for a visitor to see that such a small city with just a little more than half a million inhabitants has been able to produce many repeaters in order to offer better service and communications to radio amateurs. We have in Panama various organizations of radio amateurs which we should mention. Liga Panamena de Radioaficionados has the leadership in Panama because the majority of radio amateurs throughout the Republic are members. We would also like to mention Radio Club de Panama, another outstanding organization, and also Asociacion de Radioaficionados and Club Experimentadores de Colon. There is another organization that we would like to bring to your attention; it is the Club Geminis de Panama. All of its members are also part of the firefighters division of Panama, and as radio amateurs they have been one of the most outstanding clubs in Panama. Finally, I should mention the Canal Zone Amateur Radio Association, an organization that was founded when the United States was administering the Canal Zone territory. Most of the members of this club are US citizens, and it is one of the most active clubs, especially on HF.

With this information, I feel that I have presented a general view of amateur radio in the Republic of Panama, which offers three classes of licenses. Class A is for those radio amateurs who have technical capacity in the electronics field and have passed the correspondent test in addition to the Morse-code and the general-theory exams. Class B is for those who pass only the theory and Morse-code exams. Finally,

EQUIPMENT

The rapid development in radio communications makes radios become out of date quickly, and it is difficult to win contests without the latest gear. In countries where there are hundreds of thousands of hams, many manufacturers compete with one another to sell more and more advanced equipment.

But in Poland, where there are only 12,000 or so hams, the situation is quite different. If they have the money, Polish hams buy American- or Japanese-made products. But if that is not the case, they construct their transmitters themselves. Individual construction is nearer to the spirit of amateur radio than buying ready-made gear; in the past, designing and building stations contributed significantly to the advancement of the state of the art. At any rate, no Polish plant makes radios for hams, and very few amateurs can buy gear from abroad.

So how do they shift for themselves? Radio amateurs belonging to the Polish Scouts Association have some opportunities to obtain gadgets from military stores. Most often, they are given obsolete gear needing repair. Other hams find schematics of transceivers in magazines such as *Radio Electrician*, and some hams publish their ideas.

Recently, the bulletin of the PRAA (Polish Radio Amateurs Association) contained details of a 5-band shortwave receiver, a 10-MHz heterodyne receiver, and a frequency synthesizer. In bulletin no. 4, there is a description of a new version of vfo and a mixer. Usually, the lack of parts makes building foreign designs impossible. In technical magazines, one occasionally comes across information on Polish parts. For example, in May it was announced that new 9-MHz SSB filters are being produced. These substitutes for the renowned XF-9B are being made by Omig, which will also be making PP-9-A1, PP-9-A2, and PP-9-A3 filters.

As you can see, things look rather gloomy, but the Technical Commission of the PRAA has worked out a plan for improvement in the near future. It was decided to put up more measuring laboratories which will enable hams to convert military surplus and test transceivers manufactured in Poland. For example, Zwus will soon be manufacturing an AM heterodyne receiver, a reflectometer, an electronic switch, and the 12 AVO aerial. The Technical Commission will get professional equipment which is no longer in use and will distribute it to radio amateurs through the PRAA District Departments. To discover the needs of radio amateurs, two polls were conducted and published in the bulletin of the PRAA. One of the polls referred to the general needs and finances of Polish hams. Every ham in the survey answered questions relative to his wants and needs in components, conductors, cables, sub-assemblies, and test equipment. Additional polls will ask about needs for services, documentation, and technical literature.

The Technical Commission appealed to all radio amateurs for cooperation and asked all industrial electronics plants to begin producing the basic equipment. We hope that as a result of Poland's economic reforms, some plants might say yes.

SATELLITE-REPEATER COLLISION

The European (Region 1) frequency allocation on 2 meters is 144.0–146.0 MHz, only half of the 2-meter band in America (Region 2). A rapidly-growing ham population using 2-meter repeaters has emphasized the need for more repeater channels.

In Sweden, as well as in the other Region 1 countries, there are only 10 repeater channels, designated R0 through R9. Here we usually say only the repeater output frequency, contrary to common US practice to say both the input and output frequencies, e.g., 21/61 for 146.21 in and 146.61 out. Our channel separation is 25 kHz and repeater input is always −600. Channel R0 is 145.600 and R9 is 145.825. All Japanese 2-meter gear is made in three versions, one for the home market where no repeaters are allowed (yet), one E-version for Europe, with limited frequency coverage but with a 1750-Hz tone oscillator as repeater-opener, and one A-version for America.

With the Phase IIIB satellite up and active, severe interference is expected within the repeater coverage for channels R8 and R9, 145.800 and 145.825 MHz respectively.

Solutions

The widely-discussed solution to this problem is to abandon channels R8 and R9. This would mean a remaining maximum of only eight repeaters in a wide area in order not to cause unnecessary interference. Those living in densely-populated areas in the US and elsewhere who can easily access twenty or more repeaters can imagine the problem. There is heavy opposition against moving repeaters 1 MHz lower, i.e., into the 144-MHz band segment, which furthermore is against the Region 1 band plan.

What else? Well, the probable solution will be repeaters on so-called X-channels, i.e., channels split by 12.5-kHz separation. The industry already has European versions of 2-meter equipment capable of this new channel separation. However, interference from repeater channels on both sides is to be expected with existing equipment having a frequency swing designed for 25-kHz separation. In the beginning, repeater traffic on 145.800 and 145.825 MHz will be shared with satellite traffic, but these two frequencies will probably be abandoned eventually.

QRZ VS. CQ

Or, what's wrong with an old-fashioned CQ call? We sure live in a rapidly changing world. However, sometimes you hesitate and think for a while. Habits change; language changes as well as usage. Dialing across the bands, especially during an SSB contest, gives you a chance to observe the operating techniques used. In such a contest, you more and more often hear "QRZ Contest," and a regular "CQ Contest" is getting rare. According to the Q-code abbreviations, QRZ? means "Who is calling me?" Many of those using QRZ instead of CQ should never get a QSO if the answering station would respect what QRZ? stands for! Is maybe the feeling of being a "big gun" driving us to change old practice? Who will admit that they have to call others? No, probably it is higher status giving the impression that others are always calling them. Would you call this radio-amateur psychology?

DX BULLETIN

SK3SSA is one of many stations transmitting bulletins for radio amateurs in Sweden. This bulletin station is operated by Lars SM3AVQ and transmits in RTTY. There are other SSA bulletin stations on both HF and VHF, on CW, SSB, and FM. Through voluntary efforts by a few dedicated hams in Scandinavia, we can enjoy the superb weekly "DX Bulletin" issued by the Southern New England DX Association. In Denmark, OZ1DJY picks up the RTTY bulletin on 20 meters at midnight local time. During the week, he retransmits it to SM3CFV, who sees to it that the "DX Bulletin" can be added to the domestic "SSA Bulletin" on RTTY each Sunday morning on 80 meters. An excellent service where RTTY is the perfect mode of transmission.

TELEGRAPHY

A lot has been written and said in support of or against CW. But the net outcome is that there is no significant sign of shrinking CW activity, and the CW enthusiasts are getting more organized in order to promote CW. Their arguments are numerous, e.g., better utilization of the frequency spectrum, minimal equipment needs, last chance if everything else fails, and so on. The argument I like best is "CW is fun," and so do many who contribute to the promotion of CW.

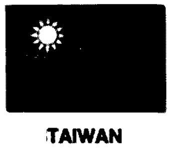
Various groups and clubs have been formed in order to support CW. All of them have a common denominator in their bylaws: Telegraphy (CW) is considered the process of mental coding and decoding of information in Morse code—no machines like keyboards and CW readers are allowed. Assistance is offered to all who are interested in learning the code, and adherence to the recommendations of IARU and the regulations of the respective national radio society is mandatory.

Typical activities of the German "Activity Group Telegraphy—DL" (AGCW-DL), for example, are rag-chewing, QRP experiments, CW training courses on the air, CW bulletins, contests, awards, and regular meetings. This group has about 1000 members. The individual national AGCWs in Europe are members of the European CW Association (EUCW), a multi-national organization. Everybody interested in the promotion of CW is invited to join the AGCWs, and no particular proficiency level is required. Foreign hams may apply for an associated membership in AGCW-DL, which is free of charge. The point of contact is Ilse Mueller DL5MAI, Stoffelsberg 3, D-8860 Noerdlingen, Federal Republic of Germany.

The High Speed Club (HSC) founded in 1951 is another CW group. It follows the same fundamental guidelines mentioned earlier but requires some personal achievement in CW by its members. In order to join HSC, one should be able to complete a CW QSO of 30 minutes duration at 25 wpm with solid copy and excellent keying. Five recommendations by HSC members confirming this achievement and 8 IRCs are all you need to apply for membership. Again, membership is free of charge. Therefore, do not confuse HSC with groups using similar logos and charging annual fees.

The HSC is also a member of EUCW and has more than 1100 members in 48 countries. Its club station, DL9HSC, is active on all bands and issues the special DOK number, HSC, for the DLD award. The point of contact is Ernst Manske DL1PM, Ansgarstrasse 14, D-2105 Seevetal 11, Federal Republic of Germany.

"Outrageous" may be your comment regarding a speed of 25 wpm. But there are thousands of hams who communicate regularly at this and even higher speeds comfortably. And there is much more in store. Once you have mastered 40 wpm, you may join the Very High Speed Club (VHSC) administered by PA0DIN, D. J. Hoogma, Schoutstraat 15, 6525 XR Nijmegen, The Netherlands. And in case you are looking for further challenges, ask ON5ME about the super and extremely high speed clubs, SHSC and EHSC! In any case, being a high speed fan or not, it is fun to celebrate the art of CW, to promote it by good operating practices, to give a hand to those who want to participate, and eventually to join one of the groups signaling "CW spoken here."



TAIWAN

FLASH

The Chinese Telecommunications Authority has finally approved the request of Italian hams to operate their rigs and calls followed by BV portable. So far, there is no further information received from the ARI about their boys' departures and arrivals. They are required to contact CRA (China Radio Association) for necessary arrangements in this regard.

It has also been learned that permission will be given to a PA ham to be the second operator in the BV2A if he holds a valid and equivalent license issued by his government to operate on 14 and 21 MHz.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Ever play this game? Take one letter—let's say "V". Well, that is either the first few bars of Beethoven's fifth or a common test signal on CW. Two letters? How about those two, back there—CW; or, being involved with radioteletype, we could use its test signal, RY. Three letters? That's easy—FSK. And four letters can be either AFSK or, you asked for it, RTTY! But how about five letters? This month we will take a look at five of the hottest letters to hit RTTY, and they spell AMTOR.

Let's start out by dropping back a bit and examining some of the fundamentals of radioteletype communications. As we have noted before, the commonly used RTTY code is the five-level Murray, sometimes called Baudot, code. Each letter is represented by a unique five-bit code, with most of the codes doubling to represent a figure or punctuation, by use of a shift into a second character set. One of the basic problems with this scheme is that in the world of radio, interference is a given. It is easy to see what would happen to a character code if any of the five bits were randomly changed from mark to space, or vice versa—the resulting character would be incorrect. Now, it might be possible to find or correct the character in plain text copy, using sophisticated computers or a good proofreader; but in code groups, data, or weather reports this would be impossible.

Various schemes have been devised to allow for error correction of bit-mangled characters. One technique, used with the American Standard Code for Information Interchange (ASCII), is to add a "parity" bit at the end of the character code. This extra bit is set at either a space (0) or mark (1), determined by the number of marks or spaces within the character code. The end result is to produce either an odd or even number of set (mark) bits. The result is termed odd, or even, parity, respectively.

Used over closed systems, this parity bit gives a remarkable improvement in accuracy. The receiving station is set up to reject any character in which the parity is not correct, and initiate a request for the sending station to repeat the letter or group. Just how this request is accomplished varies with the system, and since we will be getting into a parallel system with AMTOR later, I will not go into computer details here.

The problem with the parity bit is that if multiple bits are messed up, as might well happen with a noise burst, the computed parity may still be correct. Another, more sensitive, technique for error correction is needed for radioteletype, particularly on high-frequency, noise-prone circuits. Devised for commercial telex circuits, a system for Teleprinter Over Radio (TOR) has been established as an international standard. When adapted for amateur use, this system, which goes by many proprietary names, is called AMTOR. In order to error-proof the system as much as possible, a seven-unit code is used. Rather than depend on one parity bit, however, only combinations of four marks and three spaces are used. Thus, inverting one or more bits is highly unlikely to produce another recognizable (four-mark, three-space) code group. Additionally, code groups should be chosen so that a one-bit change or inversion would not produce a legitimate group. This is analogous to the Gray code, which is a modified binary code which eliminates ambiguity by removing one-bit transitions between digits. Of the total 128 codes available to a seven-bit system (2 to the 7th), there are 35 unique codes which fit the above criteria. Allowing for the fact that a standard Murray teleprinter uses all of the codes available to the five-bit code (2 to the 5th, or 32, characters), it would appear that such a seven-bit code would do nicely.

The resultant code is shown in Fig. 1, comparing the familiar Murray code to the CCIR code used in various TOR circuits. Observant individuals will notice that there are three Control Signal codes given after the 35 noted above, and that these do resemble some other of the codes used for letters. Well, these codes are used in a rather special fashion, which I shall be going into, and are unlikely to be confused with the letter codes when used in that way.

If all we had right now were the seven-bit codes for each letter, with some means of built-in error correction, that would be nice, but there is more. Imagine two operators talking to each other, using any mode you please, sending traffic. Now these are exceptionally well-trained operators, and at the end of each line of the message the sending station breaks for a confirmation. A quick QSL is issued to confirm receipt of each line, or a SAY AGAIN or IMI (CW for "?") is used to request a repeat of a garbled line. The sending station obeys the receiving station's request 100% of the time, and no errors are ever made in a message again. Of course, if the sending station did not hear the receiving station's answer, he would respond with "WHAT?"; the receiving station, presuming he did not get the last block, would send "SAY AGAIN", to which the sending station would respond either "WHAT??" or "SAY AGAIN WHAT?" and the whole thing would go around again. You get the picture.

Letters	Figures	Murray	AMTOR

Fig. 1.

With people on each end, the whole thing could be resolved with one quick sentence or so. But if we are going to automate this thing, a better form is needed. That is where those Control Signals come in. After some experimentation, it was formulated that the receiving station should respond to each received block with Control Signal 1 (CS1) and CS2 alternately. Thus, receipt of a duplicate Control Signal by the sending station indicates non-receipt. If the sending station does not receive the receiving station's response, it sends a request for signal repetition (RQ) instead of more data. The third Control Signal, CS3, is used to transfer assignation of the sending- and receiving-station status to the other station. In this way, either station can send or receive, alternately, with the other station concurrently confirming receipt.

So what we have at this point is a system which allows the receiving station to tell if the information received is valid, and to automatically request a repeat from the sending station if it is not. But we have done this at the expense, if you will, of two more bits of data to be sent per character. Now, if we are talking about "standard" 60-wpm RTTY, where each data pulse is 21 ms long, this would lengthen each character, now composed of seven data pulses, a start pulse, and a stop pulse, by about 25%, slowing the rate of transmission to a dismal (in this computer age) 45 wpm. Snore city!

Well, the way to deal with this is by eliminating those start and stop pulses, and speeding the whole thing up anyway so that the error correction becomes less a hindrance, and essentially transparent. Now, let me back up for a bit to explain. Conventional, if I may call it that, RTTY is know as a "start-stop," or asynchronous, system. That means that each character is an entity unto itself, starting and stopping within carefully defined limits. The system may idle for an indeterminate length of time, with a new character arriving at any time, heralded by a start pulse and ending with a stop pulse, which itself merges into the idle state. Contrast that with a synchronous system, where each character is assigned a precise time slot for its existence. By synchronizing clocks at the sending and receiving end, it is possible to eliminate the start and stop pulses by presuming that a character will be sent during a certain window of time, only. Clearly, loss of synchronization between sending and receiving stations will reduce a signal sent synchronously to garble, but there are ways of minimizing these problems.

So what do we now have? A synchronous, error-correcting way of sending RTTY which can be made to look like Murray, but which can far exceed the older system's reliability. In January we will look into AMTOR some more, and I would appreciate any of you using the technique penning me a note letting me know what you think of it. Next month, our December shopping list, a regular feature of RTTY Loop.

MULTI-BAND SLOPERS
160, 80, and 40 meters
Outstanding DX performance of slopers is well known. Now you can enjoy 2 or 3 band BIG-SIGNAL reports! Automatic bandswitching • Very low SWR • Coax feed • 2kw power • Compact • Ground or tower feed • Hang from any support 25 ft. high or higher • Easy to install • Very low profile • Complete instructions • Immediate shipment • Check ok

3 BAND SLOPER - 160, 80, & 40 Meters - 60 ft. long	$ 43.00 frt.ppd
2 BAND SLOPER - 80 & 40 Meters - 41 ft. long	$ 30.00 frt.ppd.
3-BAND NO TRAP DIPOLE, 160, 80, & 40M • 113 ft. long	$ 66.00 frt.ppd.
2-BAND NO TRAP DIPOLE, 80 & 40M • 84 ft. long	$ 49.00 frt.ppd.

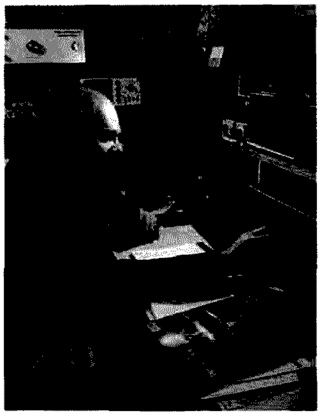
NEVER SAY DIE
editorial by Wayne Green



ASPEN HAM CONVENTION JANUARY 9-13

Gambling that Aspen will once more manage to coax some snow onto the slopes this winter, you're invited to join the usual intrepid group of hams who will descend on the town during the second week of January. This is the ninth annual ham winter conclave.

Last winter, in addition to the skiing and camaraderie, we had demonstrations and talks on the latest in packet-radio developments. The winter before, there was a symposium on proposed ham-equipment technology developments. It's always something.

At any rate, if you're a ham, a skier, gregarious, and are interested in joining the ham group swarming over the slopes of the four major ski areas in Aspen—and can manage Mexican, Chinese, Eskimo, and other weird foods—you're invited to join us on our round of the restaurants.

I have to get to the Winter Consumer Electronics Show in Las Vegas during the first week in January. This will bring me to Aspen along about Sunday the 8th, during what is called the low season (lower prices). If you bring your HT, you will be able to keep in touch with all of us on the slopes while we're skiing. We might also be able to talk while driving from Denver into Aspen and back—a long drive.

We normally pull between a half dozen and a dozen, plus a fair number of local hams—enough to properly make fun of me when I manage to trip on one of the steeper slopes and crash.

In recent years we've been staying at the Limelight, just a block from downtown. But then almost everything in Aspen is no more than a block from downtown.

Wayne Green haters: Here's your opportunity to rekindle the flames. Wayne Green lovers: Cure that silly fixation once and for all and find out what Wayne Green is really like—if you dare.

FOREIGN GIFT SUBS

The other day I contacted a chap in Czechoslovakia and had a nice chat. It didn't hurt that he recognized my call and commented on how much he has enjoyed *73*. I wondered how, in the face of the currency problems, he had managed to get the magazine. He explained that a kind American ham had sent him copies.

If you have any DX friends, you might think in terms of either passing along your copies of *73* or perhaps buying them a subscription. *73* is of particular interest to DX hams because it has more construction projects than any other ham magazine, it has an International DX news column, and it isn't filled with a bunch of useless operating news or contest results which are of interest to only a tiny minority.

Tell you what, the regular foreign surface subscription rate for *73* is $40 a year. I hate having it that high, but foreign postage rates have gone absolutely crazy and we generally find that it's possible to stay in business longer if we don't lose too much money. But I want to lend a hand to help out our DX friends, so I'll make a deal with you. If you give a DX amateur a subscription to *73* as a Christmas gift and you get the subscription in to me before Christmas, I'll go almost half of the cost. Your price this Christmas for foreign gift sub-

Continued on page 126

QSL OF THE MONTH

Everybody, including hams, seems to be talking to computers these days, and it was only a matter of time before QSLs caught up with the trend. So this month's winner, from Dave Ball WA4PDQ, is a QSL card that would be at home on the wall of the shack or in the supermarket check-out line. Dave neatly included a translation of the bar code for those of us with analog eyes, and if you look closely, you will notice that hidden within the bar code is yet a third translation of his callsign.

To enter your QSL, put it in an envelope with your choice of books from *73*'s Radio Bookshop and mail it to 73, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not in envelopes or without a book choice will not be considered.

Code Practice: Have You Seen the Light?

This simple solar cpo is the best weekend project under the sun—or bulb.

You will find this solar code oscillator handy to use whether you are just beginning to practice the Morse code or just keeping in touch. There are no batteries to wear out or to corrode—never fret about shutting the oscillator off. Yes, even years later you can pull the unit off the shelf and it will work every time (Photo A).

In most instances, solar cells are rather expensive to use in small electronic devices. Here, five solar cell pieces are taken from a 10-piece broken energy pack. You can usually purchase this pack for less than $2.00 and practically any size cells can be used for this project. Just connect the five pieces in series and you have a voltage source of over 2 volts.

The unit is assembled in a Radio Shack experimenter box measuring approximately 6 × 3 × 2 inches. Practically all of the components for the solar oscillator, except the solar cells, may be picked up at the local radio store. The LED flasher-oscillator IC can be obtained from any Radio Shack store (276-1705). You can build this solar code oscillator for less than a $10.00 bill, without the telegraph key. In fact, you can assemble it for half that price if a container box and speaker are found in your electronics junk box.

Since the LM3909 IC oscillator operates on very low voltage (1.5 V) and pulls less than 3 mA of current, solar cell pieces provide adequate power (Fig. 1). The practice oscillator may be operated in the sun or under a reading lamp. Any size 8-Ohm speaker may be used in the project. Just select the correct size and container to house the small PM speaker.

The small components are mounted upon a 2½" × 3" perforated board. Simply cut the small piece from a larger piece of stock. If a smaller size perforated board is handy, use it. There are only five small components to be mounted upon

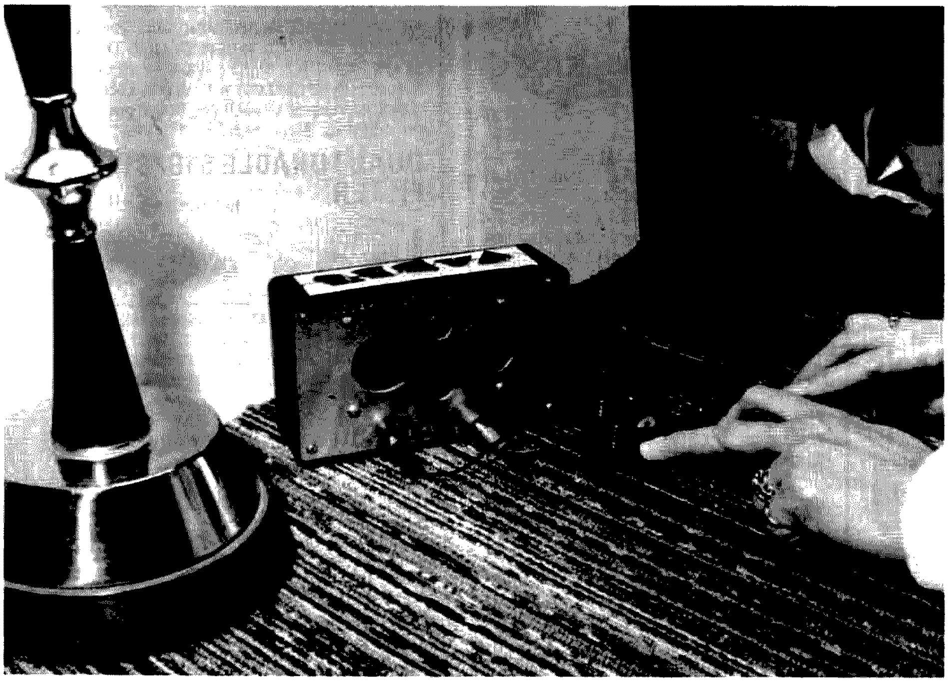

Photo A. This little solar code oscillator may be operated in the sun or under a regular reading lamp. Sufficient volume is obtained from a small 8-Ohm PM speaker.

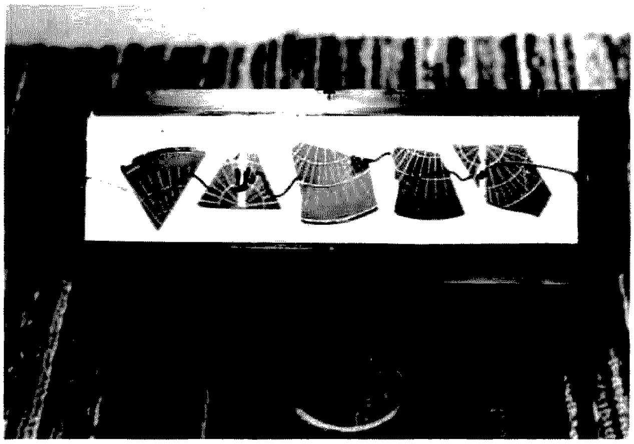

Photo B. The solar cells may be mounted on the plastic case or on a piece of cardboard. For added protection, cut a piece of thin plastic to cover the cells and cement the ends with rubber silicone cement.

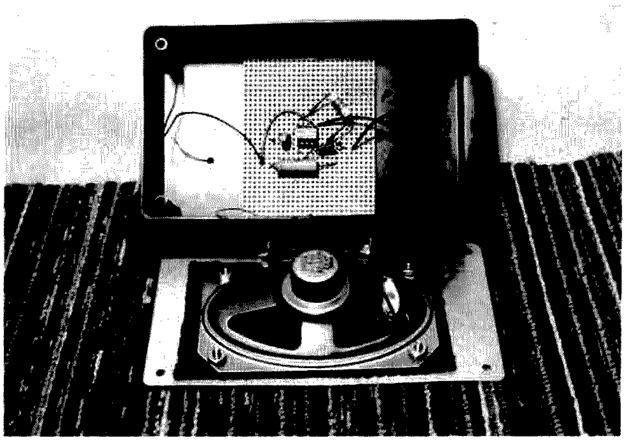

Photo C. The wiring of the small components is mounted upon a small perforated board. After the oscillator is tested, cement the board to the inside of the plastic box.

the perforated board. After all components are wired and tested, the board is glued to the inside of the plastic box with rubber silicone cement.

Mount the speaker on the aluminum cover. Some plastic boxes may have a plastic front cover. Lay the speaker on the cover and mark the speaker mounting holes. Drill several small holes or two large ones for the speaker opening. A piece of metal or plastic screen may serve as grille cloth behind the metal cover. Drill two small holes for the key jacks. Make sure they are insulated from the metal cover.

Connecting the Cells

Select five large pieces from the solar-cell assortment. The solar cells may be mounted directly upon the plastic case or on a piece of cardboard (Fig. 2). Then cement the cardboard cell arrangement to the plastic case. For added protection, you may cover the cells with a thin piece of plastic. Before mounting the solar cells, they should be connected in series.

Start with cell number 1 and connect a six-inch piece of fine wire to the top bar side of the solar cell. Any type of fine hookup or wrapping wire will do. Tin both ends of the hookup wire. Try to solder the cell-connecting wires to the center of each cell. Solder a one-inch lead to the bottom side of cell number 1 (silver). Hold the lead in place with the blade of a pocket knife. Make clean, flowing solder connections.

Now solder the small pieces of wire to the top bar of cell number 2. Flip the cells over and connect another one-inch piece to the bottom side of cell number 2. Connect all five cells in this manner until all cells are wired in series. Solder a six-inch connecting wire to the bottom side of the last cell (5). Under direct sunlight, you should generate from 1.5 to 2.5 volts from the solar cells.

Place a dab of clear rubber silicone cement on the bottom side of each cell. Turn the cells over by holding on to the wire ends. Press the cells in place. Be careful not to press too hard and break a cell. Line the cells up in a row. The cells may be placed close together by curling the small hookup wire. Let the cement set for a couple of hours (Photo B).

Wiring the Circuits

First, mount the IC socket in the middle of the perforated board. Bend over socket terminals 1 and 5. Temporarily, this will hold the socket to the mounting board until all wiring has been completed. The small resistor and capacitor are mounted as they are wired into the circuit. Stick the terminal wires through the perforated holes near the IC terminals. Solder the speaker and solar-cell wires after inserting through the small holes.

Start wiring up the oscillator with the six-inch speaker wires connected to terminal 5 of the IC socket and R1. Solder the long negative wire from the solar cells to the negative terminal of C2. The positive wire of the cells is soldered to the positive

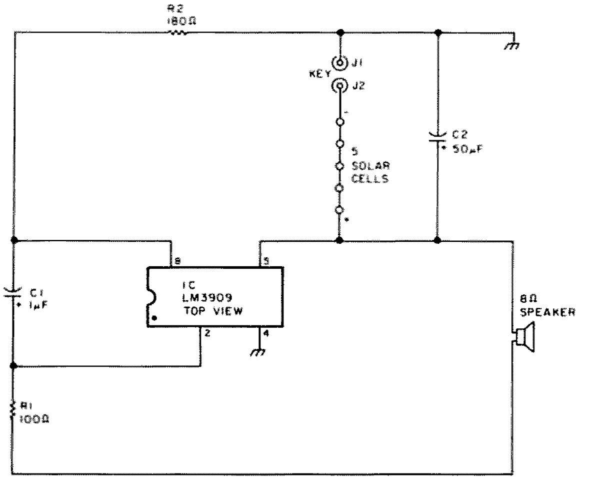

Fig. 1. The oscillator circuit is built around an 8-pin LM3909 IC chip. This small IC pulls less than 3 mA at 2 volts, making an ideal solar project.

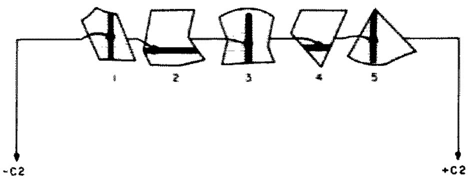

Fig. 2. Select five large solar-cell pieces from the 10-piece assortment. Connect all cells in a series arrangement.

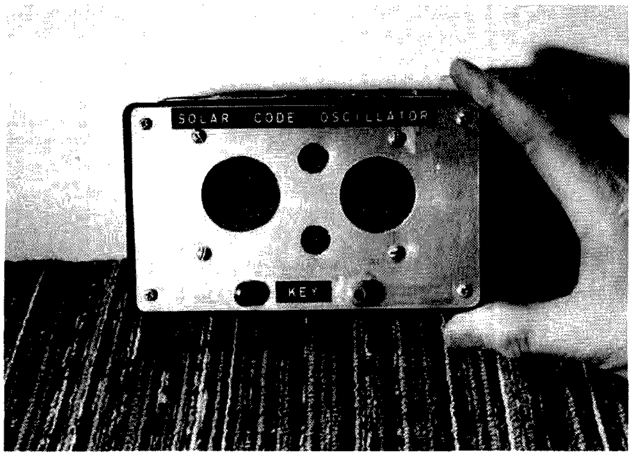

Photo D. Close-up view of the small oscillator. In this model, a metal front panel was used. The speaker holes may be drilled out with a small bit or with a circle cutter.

Parts List

J1, J2—banana jacks (Radio Shack 274-725 or equivalent)
C1—1 uF, 16 V electrolytic capacitor
C2—50 uF, 16 V
R1—100-Ohm resistor, 1/2 W
R2—220-Ohm resistor, 1/2 W
IC—LM3909 (Radio Shack 276-1705 or equivalent)
S1—8-pin IC socket (Radio Shack 276-1995 or equivalent)
Solar cells—10-piece broken energy pack
Crescent solar-cell chips, #P42,749—25 for $10.95 (Edmund Scientific Co., 101 East Gloucester Pile, Banington NJ 08007)
Solar Cell Experimenter's Assortment, S112—$7.95 (Solar Amp, Inc., PO Box 2788T, Denver CO 80227)
Speaker—any size (2- to 4-inch) PM speaker
Miscellaneous—Cabinet, telegraph key, hookup wire, and hardware

terminal of C2. Connect two four-inch hookup wire leads to the key jacks. Ground the lead from the black female jack. Solder the red jack lead to the negative terminal of C2. Don't forget to ground terminal 4 of the IC socket (Photo C).

Double-check all wiring connections with the circuit diagram. If a VOM is handy, check the voltage and solar-cell polarity leads. The positive terminal of the solar cells must be soldered to the positive terminal of C2 and terminal 5 of the IC socket. Usually, the top bar terminal lead of cell 1 is the negative terminal. Of course, the code oscillator will not perform with the solar-cell polarity reversed. You cannot ruin the IC since the low voltage and current is developed with the solar cells; the IC is not damaged with the wrong polarity.

Mark the terminals of the IC socket with a black felt pen or grease pencil. Plug in the LM3909 IC chip with the small dot at terminal 1. Insert the telegraph key and start to tap away. You may find the tone of the oscillator changing somewhat when placed near or out of the light. If the sunlight is too bright, just cover up one of the cells. ■

CES INTRODUCES THE NEW 510SA "SMART PATCH"

The State of the Art Simplex Interconnect

Communications Electronics Specialties introduces the CES 510SA "Smart" Simplex Autopatch, with many important new features never available before: • Three digit control codes with user programming. • A sophisticated toll restrict provides positive long distance lock out. • Time-out and COR activity timers with warning beeps and digital programming. • Rotary or DTMF dialing. • Phone line in-use detector prevents interrupting a call in progress, and sends unique CW sequence. • Phone ring detection logic enables unique CW sequence. • Digital programming of the sample rate and width, and noise gate sensitivity control, for easy interfacing with most radios. Simple and direct connections to radio.

Options available: • Smart CW identifier with unique CW messages for each patch function. • FCC type accepted phone line coupler. • Special tone squelch kit to operate patch through repeaters.

CES

The 510SA — the newest advance in interconnect technology, from the innovators at:

Unlimited Guarantee for Power Supplies

Plan for the worst and you'll get the best, says KCØEW. He may be right.

Bob Myers KCØEW
729 Dawn Avenue
Ft. Collins CO 80524

Sometime between opening that first "guaranteed-easy-to-assemble-in-one-hour" kit and building your own home radar defense system, you're going to have to build a power supply. There's no getting around it—most transistors hate house current, and 800 volts from D-cells is a little impractical. Fortunately, power-supply design doesn't have to be complicated. Granted, there are many, many ways of getting from 117 V ac to something usable, and some of 'em take a Nobel nominee to understand. But if you're not looking for the *most* efficient, 10¢/Watt, state-of-the-art, 10-kW supply in a shoebox, power-supply design can be fairly simple. It won't be elegant, but it'll work. And work pretty well, too.

Any ac-to-dc supply performs two basic functions: rectification and regulation. Simply put, this means changing the ac supplied by the line to dc and maintaining the output voltage (or current) at the desired level. Some designs, of course, are going to do these jobs better than others; they may add other features, such as multiple outputs, current limiting, etc. We'll cover some of these in this article, but what I really want to cover are some basic ideas and rules for a simple power-supply design. By the time you've finished reading, you'll have designed a usable supply for your bench. Well, OK . . . you can finish the rest of the magazine first.

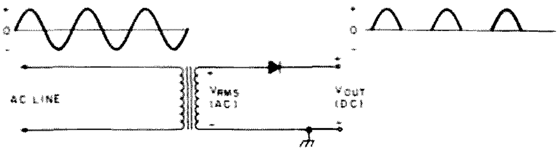

Fig. 1. Half-wave rectifier circuit.

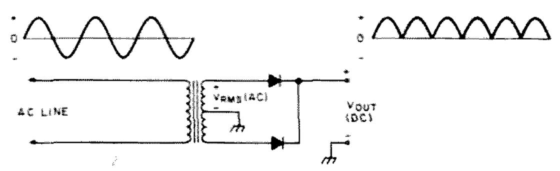

Fig. 2. Full-wave rectifier circuit.

First, a few generic rules for successful designs. Machinists have an old established rule: Spend five hours measuring and five minutes cutting. The same applies to any design. Mistakes on the drawing are easily corrected with an eraser. Mistakes found during construction are often corrected by pitching the whole thing and starting over. Myers's First Rule for Successful Projects: Get it right on paper first. Also, let's not forget that we really want to design for the worst case always. For example, what is the most current we'll ever need from our supply at a given voltage? How many outputs are we going to need now and in the future? Once you've determined your worst-case numbers, throw in a little belief in Murphy by making them worse. If I'm going to be powering some TTL, say 5 V at 1 A maximum, I might design for, say, 5 volts at 1.5 A. The extra half Amp might cost me a little bit extra, but I'll never regret putting it in. With that out of the way, let's get on with the design. For the sake of discussion, let's go ahead and build the 5-V, 1.5-A supply I just mentioned.

We know we want a solid five volts at half an Amp, and all we've got to work with is the 117 volts ac coming out of that hole in the wall. First, we'll have to get the voltage down to something reasonable and somehow get it into dc. Fortunately, there's a simple way to change ac voltages around at will—the transformer. Following a step-down transformer ("step-down" because we're going from a high voltage to a lower one), we'll need a rectifier to change the ac to dc and filtering and regulation stages to smooth out the dc output and hold it at a constant level.

We'll begin with a look at rectifiers. A rectifier is anything that changes the back-and-forth, both-directions-at-once alternating current coming out of the transformer to a flow in one direction only. Of course, the lowly diode is ideal for this—all it ever does is conduct in one direction only (well, maybe it does a little more than that, but we'll look into diodes in more detail later). Putting a diode in series with an ac source (in this case, the secondary of the transformer) will give us a sort of dc. During half the ac cycle, the diode blocks the current and no power flows. This scheme is shown in Fig. 1 and is called the

half-wave rectifier circuit, since only half the wave is used. It's cheap and simple, but the half wave not passed by the diode is lost—we can get no power from it. If we were to smooth out the half waves coming out of this circuit, the dc voltage (the average of the half waves) would only be about 0.45 times the rms output voltage of the transformer. This is due to the fact that the output of the half-wave circuit is zero half the time. What we need, it seems, is a rectifier that will let us use the other half of the ac cycle, too.

Fig. 2 shows a full-wave rectifier. The two diodes allow current to flow during the full cycle, with each diode conducting half the time. Now that we're using the full cycle, the average voltage out is 0.9 times the transformer secondary's rms output. (You may have heard rms, or "root-mean-square," voltage described as the "equivalent dc voltage" or, in other words, the dc voltage required to equal the ac in power. So, we're using about everything the transformer could give us.) But notice that the full-wave circuit as shown requires a transformer with a center-tapped secondary. This cuts the ac voltage available in half, since we're only using half the secondary at any instant. This, of course, is going to limit the dc output we can get, and we've got the extra bother of having to find a center-tapped transformer. Hmmmm. What we really need, it seems, is some way to get at that other half of the ac while not needing that third wire. Enter the bridge, shown in all its glory in Fig. 3.

A little thought while looking at this circuit, keeping in mind the fact that diodes conduct in one direction only, will convince you that it works. What we have now are two diodes conducting during each half of the wave, one pushing and the other pulling. And we'll get all the power we can ever hope for.

Diodes being fairly cheap, we'll usually opt for the full-wave bridge as the rectifier of choice. The only time you might want to consider the two-diode full-wave circuit would be for certain high-voltage transformers which simply aren't made for use with any other circuit. These usually have fairly light insulation around the center-tap, which might break down when used with the bridge. Note that this applies only for high-voltage work—for the voltages we've been talking about, it's a pretty safe bet that any transformer will work if it meets our other requirements.

Remember, the average dc output from either full-wave circuit is 0.9 times the rms voltage from the transformer secondary. The maximum dc voltage available would be obtained by putting a capacitor across the output, which would then charge to the peak voltage of the ac, or 1.4 times the rms voltage. This represents the highest voltage that can be obtained from any simple transformer/rectifier circuit. What we can reasonably expect out, then, will fall somewhere between these two values. The next two stages in the power supply will tell us what the output will be and what the transformer output has to be to get there. But first, a bit more on the diodes in the rectifier stage.

Most of the time we'll be using silicon diodes for our rectifiers, and while these are pretty simple parts, there are a couple of things to watch. The first, the diode's current rating, is pretty straightforward. Just make sure the diode is going to be able to handle all of the current you're going to put through it, plus our usual safety margin. For the 1.5-Amp supply we've been talking about, 3-Amp diodes might be a good choice.

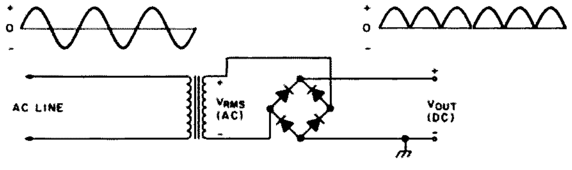

Fig. 3. Bridge rectifier circuit.

The other item we've got to worry about is one that is often overlooked: the peak-inverse-voltage, or piv, rating of the diode. While it's normally assumed that diodes will conduct one way only, you can't push them too far. If the reverse voltage on the diode exceeds the piv rating, the diode may break down and conduct in the wrong direction. Besides being bad as far as the operation of your rectifier is concerned, the large currents going the wrong way can quickly fry the diode.

The inverse voltage you'll have to worry about depends, of course, on the secondary voltage of the transformer and also on the type of rectifier circuit chosen. While the bridge will only put 1.4 times the secondary's rms output across the diodes, the half-wave and the two-diode full wave will put 2.8 times the rms voltage on them. Therefore, if you're running a 10-volt secondary with a half-wave circuit, the diode is going to have to withstand 28 volts placed backwards across it every half cycle. (This assumes that the load is nothing but a capacitor, which is going to charge to the peak voltage as mentioned earlier. But remember, we're always going to design for the worst case.)

With the voltage stepped down to something reasonable by the transformer and converted to dc by the rectifier, all we have to worry about now is smoothing out the bumps left over from the ac and trying to hold the output stable. This can be quite a challenge to the power-supply designer, but there are a few simple techniques we can use to get a usable supply design easily.

Smoothing out the pulsing dc from the rectifier is the job of the filter, which comes right after the rectifier. The simplest arrangement is to use a capacitor or capacitor and inductor combination to remove the ac component remaining in the current. The capacitor, usually a large aluminum electrolytic type, is placed across the output of the rectifier stage. The capacitor looks like a short to the ac component, while blocking the dc.

Another way to look at it is to consider the capacitor as a place to store energy; during the times that the voltage from the rectifier is dropping off, the output is supported by the charge stored in the capacitor.

Either way, the bigger the capacitor and the lighter the load, the higher the output voltage will remain. This situation can be improved somewhat by adding an inductor before the capacitor, in series with one side of the supply as shown in Fig. 4. This is called a choke-input filter stage. Here the inductor acts to block ac while passing dc. We can also look at the inductor as an energy-storage device and say that

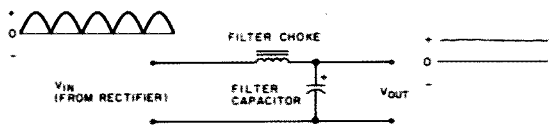

Fig. 4. Choke-input filter.

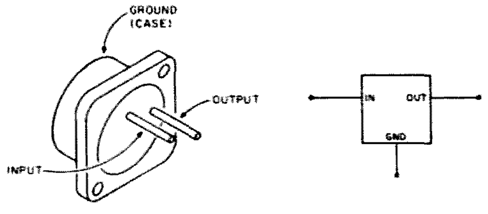

a) TO-3 PACKAGE   b) SCHEMATIC REP.

Fig. 5. The LM309 voltage regulator.

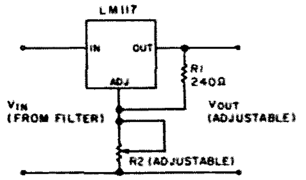

Fig. 7. Variable-voltage supply, with R2 as a potentiometer.

the current is maintained by the inductor (from energy stored in the magnetic field of the coil) during those times when the output of the rectifier is dropping off. Either way, the inductor aids the capacitor in maintaining the output at a constant level.

Capacitor-input and choke-input filtering stages are often all that is needed to provide for an acceptable dc output. But the calculations for proper design of these stages can get somewhat involved, as is finding the proper choke, etc. Fortunately, there are some simple regulating circuits which can make this job much simpler, at least for the supplies we'll want to build. So, we'll just use a large filter capacitor to get rid of most of the ac ripple and let the regulator handle the rest, along with the job of fixing the output voltage.

For light to moderate current requirements, at voltages up to about thirty volts, there is nothing easier than putting a voltage regulator IC in your design. These are integrated circuits which look a lot like power transistors from the outside, but are fairly complicated little pieces of hardware on the inside.

A regulator IC can hold your output voltage stable to within a couple of percent or better, from zero to full load. One of the more popular, the LM309, is shown in Fig. 5. Notice that it has only three leads—the input, the output, and ground. With 7 volts or higher across the input and ground, the voltage from output to ground will be held at 5.05 volts, plus or minus about a quarter of a volt (according to my trusty 1978 *National Semiconductor Linear Handbook*). And, in the TO-3 package (the big, flat can power transistors come in), it's good for a solid 1-Ampere output current. Not bad for a part that'll set you back maybe a couple of bucks at your local parts palace.

While this is almost ideal for our design (it's a little light on current, but there are higher-output versions available—up to 5 Amps and higher in some cases), you should know about the little item shown in Fig. 6. This is the LM117 adjustable regulator. Where the 309 gave us 5 volts out, no questions asked, the 117 allows you to set the output voltage at any point up to a maximum of 37 volts. This is done by connecting two resistors to the ADJ lead, one going to ground and the other to the output. The output voltage is given by:

$V_{out} = 1.25 \times (1 + R2/R1)$.

R1 is usually a few hundred Ohms (the National Semiconductor book suggests 240 Ohms) and R2 is chosen for the desired voltage. Rearranging the above formula, assuming 240 Ohms for R1, gives:

$R2(Ohms) = (V_{out}/1.25 - 1) \times 240$.

R2 could even be a potentiomenter, as shown in Fig. 7, to make a variable-voltage supply.

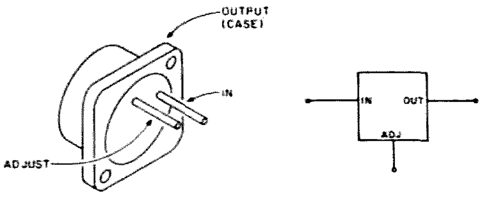
Another method of regulating the output voltage of your supply involves the use of a special type of diode called a zener. The zener diode is ideal for use as a voltage reference due to the fact that the voltage across the diode when operated backwards is very constant over a wide range of current. (Actually, all diodes show the phenomenon of reverse breakdown occurring at a certain voltage, but the zener has been so constructed as to fix this voltage precisely at a desired point and to hold to that value better for various reverse currents.) Now, how do we get from the reference level supplied by the zener to a stable output?

Zener diodes do provide a stable voltage drop, but they aren't built to handle large currents. So, the zener won't be handling the output directly. Instead, we'll put the zener at the base of a transistor which is passing the output current, as in Fig. 8. Now, since the transistor is an NPN type, the base and emitter form a P-N diode, just like the silicon diodes used in the rectifier. An interesting property of these diodes is that the voltage drop across the diode, when operated normally (or forward biased), is also fairly stable and fixed at around 0.65 volts. Since we lose 0.65 volts, then, going through the base-emitter diode, the output (the emitter) will be held at a voltage 0.65 volts less than the zener voltage. Now, what are all those other components in Fig. 8 doing there, and how do you design one of these things?

Well, for both the transistor and zener to work, they'll have to have a little current. The zener will require a certain minimum current to do its voltage-fixing trick, and the transistor will need some current into the base proportional to the current passing through from collector to emitter. The dc beta of the transistor is the number of times the current into the base must be multiplied to get the collector current. It can be as high as several hundred for small-signal transistors to as low as five or ten for the big, high-current power types.

As an example, if we're running 2 Amps through a transistor with a beta of 20, the base will need 0.1 Amps. Resistor R1 supplies both the zener current and the base current in Fig. 8. The way to calculate the value for R1 is to subtract the zener voltage from the input voltage to the regulator and divide the result by the total of the zener and base currents. The number you get is the maximum value for R1 in Ohms. As a practical rule, keep the value for R1 well under this number, say 75% of the calculated value. Too large a value for R1 and the transistor and zener won't get enough current to operate properly. Too low and you'll be wasting current in the regulator.

To make the regulator



a) TO-3 PACKAGE   b) SCHEMATIC REP.

Fig 6. The LM117 adjustable regulator.

stage as efficient as possible, we'd like to keep the base current required by the transistor as low as possible since it's wasted as far as the output is concerned. To do this, the beta of the transistor should be as high as possible. However, high-current transistors usually aren't blessed with high betas. One way around this problem is to use a special type of transistor, a Darlington. The Darlington is actually two transistors connected as shown in Fig. 9 (also, the name Darlington more properly refers to the connection of the two transistors and not to the part itself). When combined in this manner, the two transistors look like one, with a combined beta approximately equal to the betas of the two original transistors multiplied together. This can give a part with both high current capacity and high beta, making it ideal for this application. However, the B-E drop is now about 1.3 volts.

The other components shown in Fig. 8 have a place with both the IC and zener/transistor regulators. The small capacitors at the regulator's input and output help keep the output stable when subjected to short, fast disturbances (transients). The diodes across and around the regulator stage serve to protect the active devices against damage.

For example, if the supply is connected to a load which contains, say, a large capacitor, the voltage at the power supply's output may remain high for a short time after the supply has been shut off. In this case, current would try to flow back into the supply, into the regulator's output. The diode *from* output to input passes this current around the regulator so that it cannot flow into the transistor or IC and damage it. These diodes should be fairly heavy-duty units (at least equal to the rectifier diodes in current rating, and preferably a little bigger).

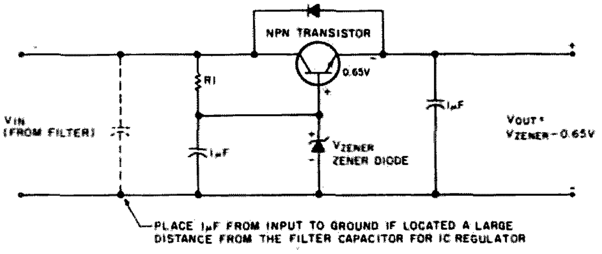


Fig. 8. Zener/transistor regulator.

Of course, sometimes it isn't voltage we want to regulate, but current. The techniques described above, with minor modification, will also work here. Since we've developed a couple of ways to tie down a voltage, regulating current is simply a matter of adding a resistor, as shown in Fig. 10. The regulator stage is now regulating the drop across this resistor, which is in series with the output. But what it's really doing is regulating the output current, thanks to Ohm's Law. The output current is, of course, now fixed at $I_{out} = V_{reg}/R$, where V is the voltage determined by the regulator and R is our series resistor in Ohms. A variable-current supply is made as easily as a variable-voltage one, by using the LM117 with a potentiometer for R2.

No matter how you configure your regulator stage, there are a few things to keep in mind. First, for any of the regulator designs we've looked at, the input to the regulator must be at a higher voltage than the desired output. How much higher depends on the type of regulator chosen, but a good rule of thumb is that you'll need at least two volts more in than you want to get out. Check the manufacturer's data sheet for the exact number in the case of an IC regulator.

Since there is a voltage drop from the input of the regulator stage to the output, this stage is dissipating power. The amount of power dissipated in Watts may be found by multiplying the drop across the regulator by the current passing through it. The maximum dissipation for the device you're using (from the data sheet) must not be exceeded. Most IC regulators will shut down before they pass enough current to cook themselves, but either way your supply won't work. Also, the data sheet for the IC regulators will list a maximum input voltage for the part. Check all the specs before designing in any part.

Well, with all this behind us, let's build a supply. We'll choose a full-wave bridge for our rectifier, which tells us that the output will be somewhere between 0.9 and 1.4 times the rms out of the transformer. Since we wanted a 5-volt supply with a 1.5-Amp maximum output current, let's find a transformer that can give us at least 5/0.9, or about 5.5, volts out at, say, 2 Amps.

But wait—we're going to lose at least two volts in the regulator stage, so what we really need is at least 7.5 Vrms from the transformer. And notice that I said two Amps—not only am I being a little conservative here, but I know that some current is going to be lost in the regulator.

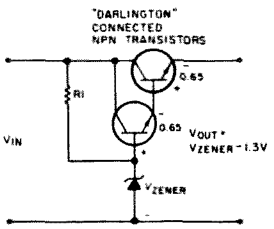

Fig. 9. Darlington configuration.

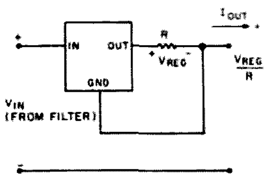

Fig. 10. Regulated-current supply.

Well, a flip through the latest Radio Shack catalog shows that they've got an 18-V, 2-A center-tapped model available (p/n 273-1515). We could either use half of the secondary (9 Vrms) for this supply, leaving the other half free for, maybe, a second output, or we might use the two-diode full-wave rectifier instead and make use of the center tap.

Looks like we'll switch over to only two diodes for our rectifier, since I really don't need a second output. (Again, one of the advantages of designing before I start building—I can change my mind!) Adding a capacitor after the rectifier will filter the resulting dc sufficiently for the regulator to handle, if we stick to a rule of thumb of about 3,000 uF per Ampere. Since we want 1.5 A out, we'll put at least a 4,500-uF cap here. Since the maximum voltage this cap will see is 1.4 times the rms out of the transformer, this capacitor should be rated for at least 1.4×9, or 12.6, volts. Derating an aluminum electrolytic by at least 25% is always a good idea, so the minimum specs for the filter cap call for a 4,500-uF, 17-V-dc unit. Again, the Radio Shack catalog lists a good choice—their p/n 272-1022 is a 4700-uF, 35-V-dc part which should work just fine.

Moving now to the regulator, we can instantly rule out the LM309 as not having enough current-handling, being rated for only about one Amp. While there are heftier 5-volt regulators available, let's try an adjustable regulator, just for the experience. The LM117 we mentioned earlier is rated at

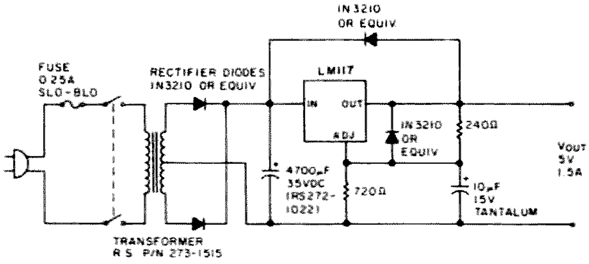

Fig. 11. Final design of the 5-V supply.

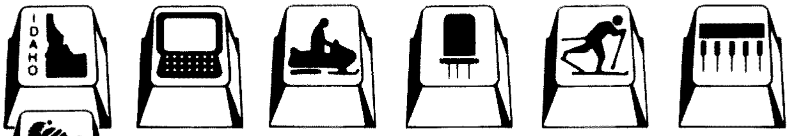
1.5 A, or we might play it really conservative and go with a higher-current adjustable such as the LM350. Either way, we can get R2 from our formula, assuming 240 Ohms for R1: $R2 = (5/1.25 - 1) \times 240 = 720$ Ohms. This isn't a standard value, but we can get 720 Ohms by putting a 330-Ohm and a 390-Ohm in series, or hunting through a pile of 680s and 750s with an ohmmeter. Obviously, the closer R1 and R2 are to their design values, the closer the output voltage will be to the desired level.

With R1 and R2 chosen, all that remains is to include the protection diodes and the capacitor at the output (usually about 1 uF) to complete the design of our 5-V supply. The final design is shown in Fig. 11. Notice that a couple of other amenities, such as a switch, a pilot light, and a fuse, have been included in the final schematic. A fuse or circuit breaker is often overlooked in home-brew designs, but you'll never regret putting one in. At the least, you might keep the supply from frying, and you might keep your house wiring from doing the same thing. The proper rating for the fuse is easily determined by remembering that the transformer action with regards to current is the opposite of its effect on voltage. In other words, if the transformer reduces the voltage by a factor of ten, then it'll only draw one-tenth the current into the primary that the secondary is putting out. Since we're going to be drawing at most two Amps from the secondary at nine volts rms, the peak through the primary should be: $I_{primary} = 2A/(117\ V/9\ V) =$ 154 mA. A quarter-Amp fuse should make sure that we catch all problems without blowing under normal operation. Use a "slo-blo" type so that the fuse won't blow from the initial inrush of current when you first switch on the supply and the juice zooms into that big filter cap.

Construction should be simple and straightforward, and the layout is as far from critical as you can get. A couple of points, though: Make sure there are no exposed points at line voltage, and be neat with your layout and actual construction. Also, it's a good idea to mount the regulator on some type of heat sink. You could either buy a commercially-made TO-3 heat sink or mount the regulator on the case of the supply (assuming you're using a metal box). In either case, be sure the regulator package is insulated from the case electrically (you can also buy little pre-cut silicone rubber pads, or cut your own), and use a good helping of silicone heat-sink goop.

Have fun designing and building your supplies. If you'd like additional info on power-supply design, either handbook (the ARRL's or Bill Orr's) has an excellent section devoted to the subject. Keep those soldering irons hot! ■



ELECTRONIC ENGINEER (RF) wanting Southern **IDAHO** sports and recreation, state-of-the-art mobile communication challenges and professional growth should consider US COMMUNICATIONS CORPORATION.

Junior and Senior grade professional RF electrical engineers with BS or MS degrees for assignments in new product development programs for exciting new mobile communications hardware/software.

RF TECHNICANS - Two year AA or equivalent education with proven record in RF Engineering Laboratory work are encouraged to apply.

AN EQUAL OPPORTUNITY EMPLOYER M/F

TS830/TS930S IMPROVED!

Yes, spectacularly! By simply adding a *Matched Pair* of top-quality Fox Tango Filters. Here are a few quotes from enthusiastic users:

. . . *makes a new rig out of my old TS830S* . . .
. . . *VBT now works the way I dreamed it should* . . .
. . . *Spectacular improvement in SSB selectivity* . . .
. . . *Completely eliminates my need for CW filters* . . .
. . . *Simple installation . . . excellent instructions* . . .
. . . *Switched filters to new 930S when I traded my old 830 . . . same solid improvement!* . . .

The 2.1KHz bandwidth Fox Tango SSB filters are notably superior to both original 2.7KHz BW units but especially the modest ceramic second IF; our substitutes are both 8-pole discrete-crystal construction. Compare the test results—Fox Tango Filters vs. Kenwood's:

On SSB with VBT Off—RX BW: 2.0 vs 2.4; Shape Factor: 1.2 vs 1.34; 80dB BW: 2.48 vs 3.41; Ultimate Rejection: 110dB vs 80.

On CW with VBT set for 300Hz BW—Shape Factor: 2.9 vs 3.33; Insertion Loss: 1dB vs 10dB! Chances are you won't need them but a new 400Hz CW pair is now available for those who insist on the very best CW reception.

COMPLETE KITS . . . . Only $170 each
FTK830 or FTK930 (2.1KHz BW for SSB/CW)
FTK830 or FTK930 (400Hz BW for CW Only)

Each includes a Matched Pair of Fox Tango Filters, all needed cables, parts, detailed instructions. Specify rig and bandwidth desired when ordering. Shipping: $3 (COD +$1, Air +$2, Overseas +$5). Florida residents: add 5% Sales Tax.

ONE YEAR WARRANTY

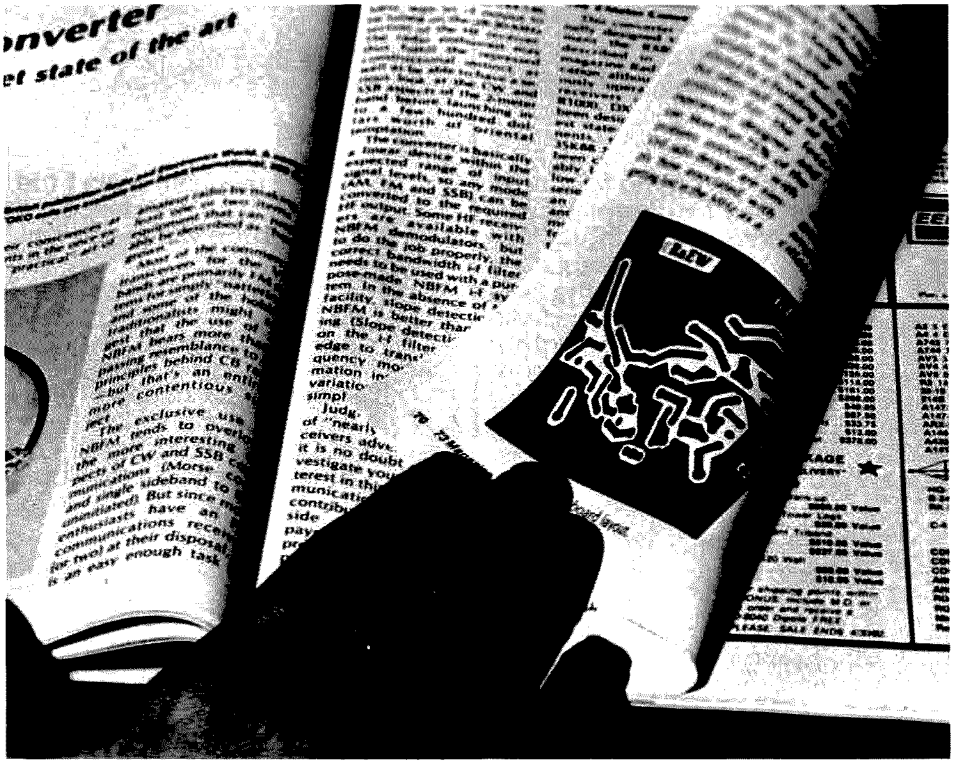
PC Boards in a Flash!

Make circuit boards without expensive equipment. All you need is a light and a fast switch hand.

How many times have you found an excellent construction article in an amateur magazine such as *73* but didn't build the thing because you had no simple, convenient, low-cost method of getting the PCB layout off the page and onto a negative? Magazines and textbooks, unfortunately, have printing on both sides of the page, making it necessary to have the pattern photographed with a copy camera for best results—an expensive undertaking. Other methods such as photocopying leave much to be desired also, due to linear distortion and problems of access to the equipment.

Well, get the junk box fired up, folks, because we're about to walk through a simple, low-cost, and quick method of making PCB negatives that will put you back into the homebrew business. It'll take a lot longer to tell you about it than it will to do it. You don't have to know a thing about photography or have a degree in chemistry to participate, so join in.



Typical article containing PCB layout. My technique offers a simple alternative for those who do not have access to copy cameras or good photocopying equipment.

This technique allows anyone to make exact-size PCB negatives (microwave fans rejoice) directly from the printed page, no matter what is printed on the reverse side (so long as it isn't entirely jet black). The model for this article was taken from a typical page in *73*, as shown in the photograph. We're going to print the whole mess (it may come out with both sides of the page showing) onto Kodalith high-contrast film, then remove what we don't want. The process requires making both positive and negative copies, but have no fear. Only two easily-mixed chemicals are used and the entire operation can be carried out at the kitchen or bathroom sink. The bathroom is better because it's easier to control dust in that area. I'll explain this further on.

First, a word about *positive* and *negative*. The pattern on the magazine page is a *positive* image—the subject, if you will. The *negative*

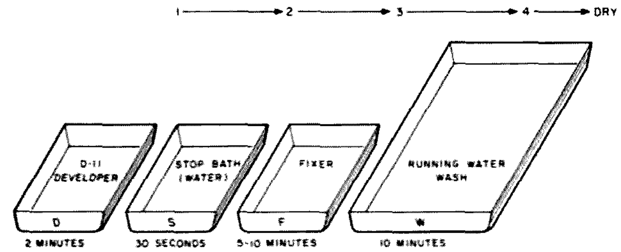


Fig. 1. Layout of trays, showing sequence of operations. Note that trays are marked for their respective chemicals. Interchanging trays and chemicals eventually results in disaster somewhere down the line due to contamination.

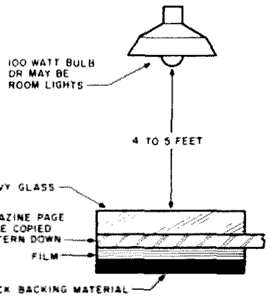

Fig. 2. This is the setup for making the first exposure directly from the magazine page.

is the first copy of that subject and is identical to the negative you get in your camera when making an ordinary photograph. By printing that negative, you get an image that looks like the subject; it also is a positive.

The photo-etching process can be done using the positive or the negative technique; we will make both positive and negative images so that all bases will be covered. (See the illustrations.)

Setting Up

First, trot down to the local photography store with the shopping list in Table 1. There are no exotic items on the list, and a well-stocked store should have everything on hand. Graphic arts people and photographers use this stuff by the ton every day.

Next, stop off at the hardware store with the list in Table 2. (All of these items can be purchased at the photo store but would cost you a bundle by comparison.) If you opt to "borrow" some of the common items from the kitchen, keep them. *Don't ever use them for food again. Photographic chemicals are highly toxic.*

Mix the chemicals. Follow the manufacturer's directions. There is no magic involved; just get in the ballpark. A few tips might be in order, however. Mix by stirring, as recommended. Sure, you can dump the whole mess into the gallon jug and shake it like mad, but this action mixes an excessive amount of air with the chemicals and the oxygen in the air causes rapid deterioration of the chemicals.

Try to mix the chemicals the day before you will use them, and store the mixture in the area where you will be developing your film. This will allow any air in the solution to escape—and you won't have to worry about temperature problems. Most schools recommend sixty-eight degrees Fahrenheit as the ideal temperature. This temperature was picked because that was the average room temperature of a house in England when the process was discovered generations ago. Photographic processes work over a wide range of temperatures, with adjustments, but we won't go into that here. Just maintain an average, comfortable household temperature.

Prepare the work area. Dust and dirt are the villains in any photographic process. Clean the work area until it shines. Remember the bathroom recommendation? Great. Turn the shower on hot for a short period of time to fill the room with steam. Turn the shower off, close the door, and let things cool off for about an hour. The steam will have settled all of the dust out of the air by the time you're ready to work.

Minimal equipment is required. The gallon jugs needed are not shown.

The work area must be light tight. The film must be opened and processed only under the illumination of your safelight, so you must seal up the windows and doors so that no great amount of outside light seeps in. I'll leave that operation up to you because how it's done depends on your particular circumstances. To check if it's been done properly, stand in the darkened room for five minutes. You'll then be able to see any obvious light leaks. Seal them up.

Lighting

You will be using two kinds of light; we will call them white light and safelight. The white light can be a 100-Watt light bulb or just the ordinary room lights if they are fairly bright. The white light should be directly over the area where you will be exposing your film. (This area is called the "dry side" of the room.) The safelight that you purchased at the photo store should have a red filter to give off a red-color light. It should have a bulb no larger than 15 Watts, and 7½ Watts is better. Hang it four to five feet away from the film-processing areas. You'll be sur-

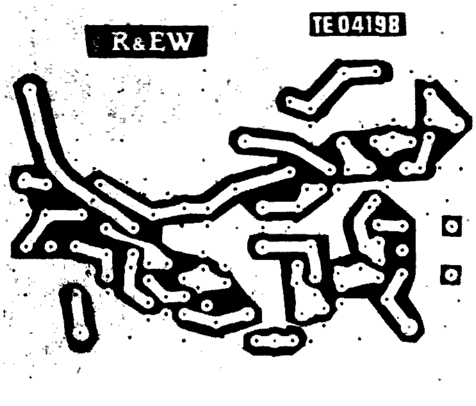

Fig. 3. A negative obtained by the process described.

A windowpane makes a quick "light box" for retouching both negative and positive. Mark on dull (emulsion) side of film only. North light works best.

prised to find that after a few minutes in this dim darkroom light you'll be able to read a newspaper. *Please take all of the usual precautions when working around plumbing fixtures and electricity.* If you are not sure about the safety of your conditions, have an expert check them out. Don't take chances.

Pour about an inch of the appropriate liquids into the three small trays (see Fig. 1) and arrange them as shown. The larger wash tray may be used on the same "wet side" of the room or set up in another area as you will be washing the film in normal room-lighting conditions. If you happen to spill the chemicals, wipe them

1. Kodalith ortho film, type 3, Kodak #2556. (This is a very thin Graphic Arts film, sold in 4″ × 5″, 5″ × 7″, and 8″ × 10″ sheets, 50 sheets per box. *Do not open except in darkroom.*)

2. Kodak D-11 developer. (Sold in powder form. When mixed with water, makes one gallon. Kodalith developer is usually used with this film but produces overly-hard blacks in unwanted areas for our purposes.)

3. Fixer. (Also known as hypo. Sold under many brand names. May be powder or liquid. Buy powder. In liquid form you're paying for a lot of water.)

4. Photoflo. (Kodak's trade name for a wetting agent that helps dry film without spots. Buy smallest container. It'll last forever.)

5. Stop bath. (A solution of 28% acetic acid and water is normally used but too much acid can produce bubbles on the emulsion. I use plain tap water only, at the same temperature as the other chemicals, for all my films.)

6. Stainless-steel tongs. (One required for handling wet film. More expensive than wood or bamboo but doesn't absorb chemicals and lasts a lifetime.)

7. Safelight with 1a red filter. (I use a 10-Watt red bulb that I know doesn't fog the film. To test: In a dark room, lay a sheet of film on the work table, place a coin on the film and turn on the safelight for five minutes. Develop the film. You should not get an image of the coin on the film if the light is safe.)

8. Red opaque pen. (I use red because it's easy to see on the film. Do not use regular marking pen. Black india ink also works well but can be quite messy.)

Table 1. Photographic materials needed.

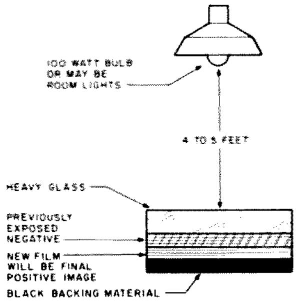

Fig. 4. This is the setup for the second exposure. The resulting positive image can be used to make your PCB.

up because they can cause ugly stains. (Suffering the wrath of others is not part of this process.) Now all of the running is done; the setup is complete, so let's get on with the fun part.

Making the Negative

Close the door, turn on the red safelight, and turn off the white room lights. Your room should be dimly lighted by only your safelight at this point. Open the film box, snip off the end of the foil envelope containing the sheets of film, and remove one sheet of film. Fold the end of the foil envelope over, place it back in the box and *close the box.* Lay the film on the black backing material—or in the contact frame if you have elected to go that route. The film is so thin that for our purposes it doesn't make any difference which side is up, but it is good darkroom practice *always* to have the emulsion side facing the subject being copied.

Next, place the pattern to be copied on the film, copy down, in contact with the film. Lay the heavy glass on top of the pack to hold everything flat and in place. Fig. 2 shows the setup for this operation. *Recheck the film box to be sure it is closed.* Switch on the white light for two seconds. Turn off the white light. The negative has now been exposed.

Developing the Negative

Remove the exposed negative from the pack and with a quick sliding motion put it into the tray of developer so that it is covered with developer solution. Rock the tray gently by lifting and lowering one corner to keep fresh developer constantly moving over the surface of the film. You will see the image pop up on the film in about thirty seconds. Continue agitating in this manner for a total of two minutes.

When the time is up, carefully grasp the film by one corner with your tongs, lift it out of the developer, and let it drip for five seconds. Slide it into the tray of stop bath and agitate it for about thirty seconds. Again, lift it out by one corner, drain it for five seconds, and slide it into the fixer. Don't let the tongs touch the fixer or the next time you put them in

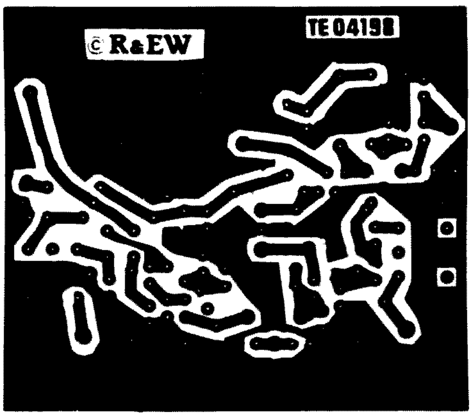

Fig. 5. A positive obtained by the process described.

the developer the fixer will contaminate it and decrease its working life.

Agitate the film in the fixer for five to ten minutes. The film will have a milky-white cast to it when you put it in the fixer. A good rule of thumb is to fix the film for twice as long as it takes for the milky cast of the film to clear. After the film has cleared you can turn on the white room lights. (Did you check to be sure your film box was closed?)

Remove the negative, which should show a good strong image at this point, and place it in the wash tray containing running water of approximately the same temperature as the processing solutions. Wash away the residual fixer for about ten minutes. Turn off the water and add several drops of Photoflo™ to the wash water. Move the film around in the Photoflo solution for about thirty seconds.

Remove the negative from the tray and hang it up by one corner to dry. Do not wipe the film. Drying should take about one hour, but if you're in a hurry you can use a hair dryer to accelerate the action. Let the film drip dry for about fifteen minutes before using this technique, and don't get too much heat on the film or nasty things will happen. Gently does it. Just be sure that it is perfectly dry for the next step.

Fig. 3 shows an example of a negative obtained by the process described.

Opaquing the Negative

Place the film negative on a clean window pane (or light box if you have one) and hold it in place with tape on two diagonal corners. A window on the north side without direct sunlight works best. Now you can examine your negative image in all its glory. The image will be reversed from that in the book—the clear areas representing the copper and the black areas representing the areas where the copper will be etched away on the final board.

The is the first stage. You may notice some of the printing from the reverse side of the printed page showing through the clear areas, but don't be concerned. The next operation will remove it.

With your red opaquing pen, color in all those unwanted spotty clear areas showing through the black, being careful *not* to fill in any clear areas that will eventually be copper. (The red ink allows light to show through, but don't worry about it. The film cannot see red light—it will look black to the film.)

Making the Positive

Back to the darkroom: red safelight on, white light off. Take a new piece of film from the box and sandwich it with your negative, as shown in Fig. 4. *Check the film box to be sure it's closed.* Flick on the white light for a two-second exposure. Run the new film through the developer, stop bath, and fixer the same way you did the first time. Wash and dry. You now have the positive that should look pretty close to that pattern you copied from the page. Tape it to your window or use your light box and spot-fill the unwanted clear areas.

A couple of notes that might help you through the learning curve: Don't be afraid to vary the times given for exposure or processing. Kodalith is a very versatile material that can perform all kinds of tricks for you. For instance, by varying the exposure times you will find that the width of lines and diameters of circles change. Not only is this phenomenon a characteristic of the film and a good indicator of proper exposure, but it can be used to make such things as QSL cards using the line-positive technique. The *Photographic Lab Handbook*, by John S. Carroll, is an excellent reference for this type of work. Eastman Kodak also has a library of publications on the use of their products, most of which should be available from your photo dealer.

The red opaquing pens recommended here are sometimes hard to come by. Black india ink is a good substitute but can be hard to see on the black image. Standard marking pens do not work too well, in my experience. The ink seems to vary widely in its light-filtering characteristics.

Thanks to my wife, Rita, for helping me with this article.■

1. 3 one-gallon jugs. (Used for mixing and storing chemicals. Must be glass or plastic, not metal. Opaque containers are recommended but are expensive. Empty plastic milk bottles work fine if you store the chemicals in a dark place.)

2. 3 glass, plastic, or stainless-steel trays. (Should be about two inches deep and larger than the largest size film you expect to use. Mark them D, S, and F. Use them for the same chemicals each time.)

3. 1 piece of clear glass, ¼-inch thick. (Should be larger than the largest size film you expect to use. Contact printing frame may be used instead.)

4. Black backing material. (Should be larger than the largest size film you expect to use. I use a sheet of black plastic foam. Material such as cloth will produce lint that will give you fits. Not required if you use contact printing frame.)

5. 1 large plastic tray or tub. (Used for washing film.)

"We've Been Boarded!"

When the Lorelei *strayed into Nicaraguan waters, hams came to the rescue. Here, the net results.*

Following is a chronological account of an event of which all amateur radio operators can be proud. This is because, beyond any doubt, it was an instance where the Amateur Radio Service was the only means by which comfort, aid, and reassurance were given to certain people who were involved in emergency circumstances.

To the best of my knowledge, all of the operators involved (whose cooperation and coordination were of critical import) were these: Art HH2A, Fred K2OGS, Bill HR1BL, Bob N6CSV, Brian, a non-amateur, Dan N6IAU, NMI (Coast Guard, Miami), N1CLS/5, YV2CPG, and myself, W9UUC.

I usually tune in my radio to the Maritime Mobile Net on 14.313 as soon as I get home (Elmhurst, Illinois), around 3:30 or 4:00 in the afternoon. This is just what I did on Tuesday, May 17, 1983. After listening for only a short time, I heard a station say he was maritime mobile with emergency traffic.

HR1BL (Tegucigalpa, Honduras), who was net control at the time, asked if anyone had a good copy on the ship. Both K2OGS (Yonkers, NY) and HH2A (Haiti) said they did. Net control asked them to move him off the net frequency. They went to 14.324, and I followed them and told them I also had a good copy on the ship.

The emergency call was from Bob N6CSV, and his signal was coming from within 12 miles of the Pacific coastline of Costa Rica. He advised that the emergency was still in progress.

He stated that he had been sailing with three other American sailing vessels on a pleasure cruise about five days out of Mexico. They all had been heading for Punta Arena, Costa Rica, when a storm came up at night and blew the four of them off course. Soon after the weather cleared and the next day had dawned, he found himself alone at sea—in touch with the others through only one of them, Brian. It was Brian who had the emergency and had contacted N6CSV by VHF maritime radio, channel 16.

At that moment, Brian came on frequency and said he was not a licensed operator, but that he understood (correctly, of course) that in an emergency situation it was legal for him to transmit. HH2A couldn't hear Brian too well, but I could, so he asked me to ascertain the nature of the emergency.

Brian informed me that he was aboard the sailing vessel *Lorelei.* He told me how his and the other two ships had become separated by about 20 miles from N6CSV. At daybreak, the three saw close to them land which they believed might be Nicaragua. Realizing that they were in that nation's waters, they immediately headed westward and stayed on that course for some time.

It was then that the reason for the emergency transmission became clear. I learned that on deck above Brian, unaware of his radio communications, was an armed crewman from a Nicaraguan gunboat. All three ships had been boarded (after Brian had thought they were in international waters), and, at that very moment, they were guarded and under orders to sail for the Nicaraguan port of San Juan del Sur.

At this time, HH2A, who could hear enough to get the picture, suggested that this called for US State Department attention. K2OGS agreed and said he would place a call to the departmental emergency number at once.

Still having the best contact with both Brian and N6CSV, I informed them both of our actions. Brian then asked me to call his brother in the States and apprise him of the situation, but ask that he not, at this time, let his wife's folks know what was taking place. At this point, YV2CPG (Philadelphia)—I believe that was his call—came in to say that he was portable in the area and would stand by in case he was needed.

Brian and I were keeping our transmissions as short and infrequent as possible to minimize the chances of having any Nicaraguans overhear, but now Brian informed me that the crisis was deepening. He had just been informed on VHF by the skipper that the order had been given that all men would have to leave the ships when they reached land and that all the women would have to remain on board.

About this time, K2OGS came back on and said Coast Guard, Washington, was going to handle everything and would be up on frequency soon.

For a long time nothing was heard and tension began to mount. N1CLS portable 5 came on and said he was at Keesler Field, Biloxi, and had a direct line to New Orleans if needed.

Finally, after more delay, K2OGS came back to say that NMI (Coast Guard, Miami) was now going to handle everything and would be up on frequency soon.

After what seemed a half hour or longer but actually was only about another ten minutes, NMI did come up on frequency. But could we

turn all transmissions over and just listen? No. NMI had such a terrible ac hum on his signal that he was very difficult to copy and was impossible for Brian. I had to continue to relay all transmissions.

NMI needed specific information, and I obtained it from Brian: the names of all ships and their documentation numbers, the home port for each, a contact phone number in the States for each ship, and the names of all persons on each ship.

NMI also wanted to know if all parties were American citizens, if all three ships had been boarded simultaneously, and where they were heading. I reported for Brian that the answer was yes, they were all American citizens, and that they were being taken to the port of San Juan del Sur. Then NMI wanted to know if they were under any kind of harassment or were being taken in forcibly.

Looking back to that Tuesday, May 17, I believe now that it was at this point that tension had been at its highest, for Brian's answer gave us our first reason to begin to feel better. No, no actual harassment, Brian said, even though there were the armed guards on all ships. In spite of this, said Brian, all three ships were keeping in continuous contact with each other via their VHF marine radios, and nobody was being threatened.

At this point, we heard from HR1BL again. He informed us that he was in touch with the American Embassy there in Tegucigalpa. While he was on the phone with them, he wanted to pass on the same information which I had relayed from Brian to NMI. I therefore gave it to him. A short while later, we learned that the embassy in Tegucigalpa was in communication with the embassy in Managua, the Nicaraguan capital.

Tension heightened once more when it was reported by one of the listeners on both the VHF channel and 14.324 that one American on one of the boarded ships had given a real tongue lashing in Spanish to one of the Nicaraguan naval officials regarding their capture and being forced to sail into a Nicaraguan port. Almost at once, however, a follow-up report cleared the air and it seemed that everybody was being very cooperative.

It is an indication that understandings were then finally being reached by all concerned, that the last transmission I logged—at 2315Z—was to the effect that at least six ships in the Bay of Coco (off Costa Rica—where N6CSV had sent out his call for help) had been listening to all that was said and reported that there was plenty of beer on ice ready for all ships returning from the high seas!

Now we come to the aftermath of the story. At approximately 0110Z on May 19 (2010 Chicago time, on the 18th), I contacted Dan N6IAU on board one of the ships which had been seized. He seemed to know me by name and asked me to make some phone patches for him.

We had a very good ragchew about the whole episode, and from it and the phone patch I made for him to his mother, I learned more about what had then happened.

It turned out that as a licensed amateur operator he had been listening to everything which transpired between me and Brian. I never asked him the reason he didn't ever transmit, but who knows, perhaps he felt the armed guards on his ship might come down at any time.

He felt that one reason they were released so quickly from San Juan del Sur was that the Nicaraguans didn't want the counterrevolutionaries in their country to get hold of the situation and perhaps blow it up all out of proportion. He also stressed how very well they all were treated.

N6IAU even mentioned the fact that they had shown the gunboat guards the weapons they had on board their ships for purposes of self-protection. The guards hadn't been at all interested and made no move to confiscate them.

Not only were they not harassed, but while at San Juan del Sur, the Minister of Defense invited his father to go to Managua for a tour! The Minister took his father around the city and bought him a steak dinner and some drinks. N6IAU said they all had been a little anxious while his father was gone, but when he returned were pleased by the report that the steak was one of the best ever served anywhere in the world!

Finally, you readers should know that N6IAU's mother said that while the State Department had kept in close contact with her and had continually assured her that they would let her know as soon as they had fresh information, thanks to amateur radio, she was able to call the State Department and be the one to report the up-to-date news!

In conclusion, I would just like to state that much of the credit for the successful outcome of this episode should go to Fred K2OGS for contacting Washington and apprising them of the situation and to Bill HR1BL for quickly reporting the details needed to our embassy in Honduras. All I did was relay information to NMI and to HR1BL when he had our embassy on the line. HH2A also did a fine job as net control.

I would like to thank Jack K4DMK (aka the Swamp Rat)—who does a fantastic job as coordinator of the 14.313 MM net—for information received to help me in the preparation of this article. ■

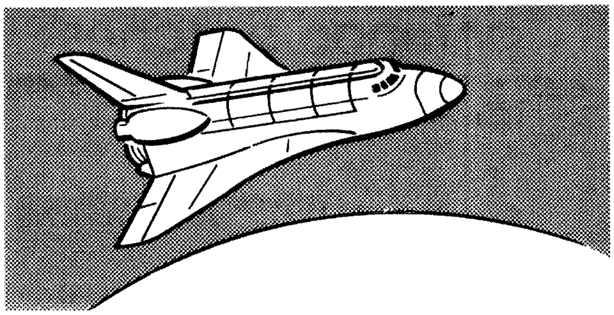
AMATEUR TELEVISION



ATV TRANSMITTER/CONVERTER

$399 delivered
TC-1 plus

- **OVER 10 WATTS PEP OUTPUT.** Crystal controlled continuous duty transmitter. Specify 439.25, 434.0, 426.25 standard or other 70 cm frequency. 2 freq. option add $26.
- **BASE, MOBILE, or PORTABLE.** Use the builtin AC supply or external 13.8 vdc. Do parades, Marathons, etc.
- **TWO VIDEO AND AUDIO INPUTS** for camera, TVRO, VCR, or computer. Wide bandwidth for broadcast quality color video and computer graphics. Standard broadcast subcarrier sound which is heard thru the TV speaker.
- **RECEIVE ON YOUR STANDARD TV SET** tuned to channel 3 or 4. Sensitive varicap tuned TVC-2L downconverter covers simplex and repeater freq. over the whole 420-450 mHz 70 cm amateur band.
- **ATTRACTIVE 10.5 x 3 x 9 CABINET.**

FCC & NASA OKs SHUTTLE VIDEO

Want a chance at seeing W5LFL live as he works 2 meters?

Its been great hearing the audio on the various repeaters, but now, if you hold a technician class or higher license, and have a TVRO capable of receiving Satcom IR transponder 13, you can repeat the space shuttle video to your fellow hams using our TC-1 plus. Just connect the composite video and line audio from the Satellite receiver to the video and audio inputs of the TC-1. Depending on your antenna, coverage will be typically the same as 2 meter simplex. Local area hams can receive with just one of our 70 CM downconverters and an antenna.

ATV 70 cm DOWNCONVERTERS

For those who want to see the repeated shuttle video, and other ATV action before they commit to a complete station, the TVC-4 is for you. The TVC-4 contains the TVC-2 module mounted in a cabinet with AC supply ready to go. Tunes 420 to 450 mHz. Just connect 70 cm antenna and your TV set tuned to ch 3 or 4 .... **$89** delivered.

TVC-4L hotter preamp for fringe areas .. **$99** delivered.

TVC-2 wired and tested module. Req. 12 vdc. MRF901 preamp stage. Varicap tuned 420-450 mHz. A low cost start at ..... **$49.**

TVC-2L hotter NE64535 preamp stage .... **$59** delivered.

TVC-2G GaAsFet preamp stage. Antenna mounting **$79**

CALL OR WRITE FOR OUR CATALOG or more information on ATV antennas, transmit modules, cameras, and much, much more. See chapter 14 pg 30-32 1983 ARRL Handbook.

TERMS: Visa, Mastercard, or cash only UPS CODs by telephone or mail. Postal money orders and telephone orders usually shipped within 2 days. All other checks must clear before shipment. Transmitting equipment sold only to licensed amateurs.

A Good-Buddy Power Booster for Converted CBs

KE4VP turned an illegal amplifier into a law-abiding citizen. You can, too.

Elliott Farrell, Jr. KE4VP
Rt 3, Box 658
Walterboro SC 29488

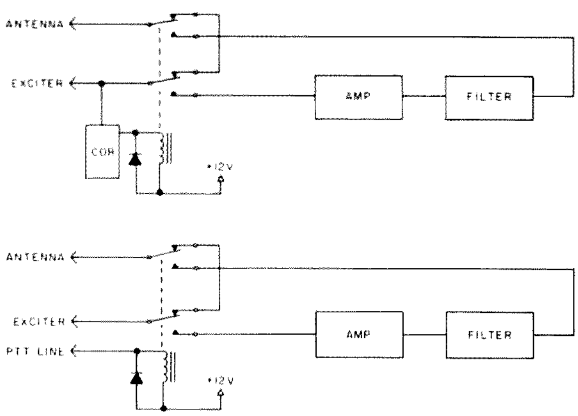

Fig. 1. Block diagram using COR (top) and transceiver PTT line.

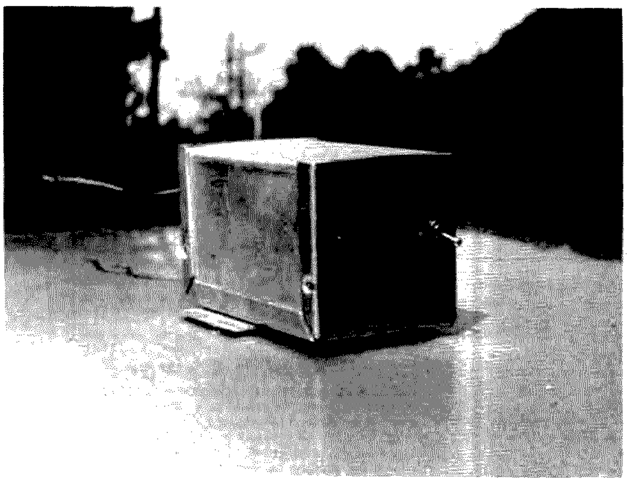
With varying degrees of success, I have converted several CB transceivers for use on 10 meters; the most recent was a Realistic TRC448. After conversion, the transmitter would produce only 1 Watt AM and 4 Watts SSB. I felt that a little more power would provide a more satisfactory mobile signal. What I needed was a small linear amplifier, preferably solid state.

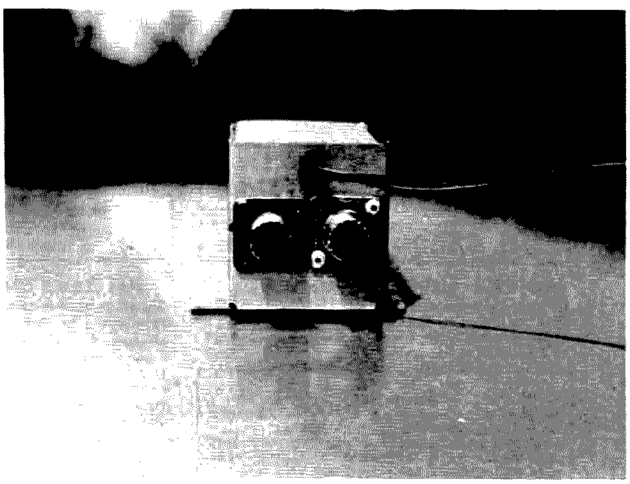
One of the primary reasons for converting a CB radio in the first place was cost, so any power amplifier used would have to be inexpensive to build. Ideally, it could be built using parts from the junk box.

After spending considerable time digging through old magazines and books, many circuits were found, but all of them failed to meet my requirements. They either used vacuum tubes (too much current drain), produced more power than I wanted (I wanted only 40 or 50 Watts), or used more than one power transistor, adding to the cost of construction. I was just about ready to forget about more power and use what I had.

A few days later I found what would possibly meet the requirements I had set for an amplifier: It was inexpensive, solid state, and had low current drain. A friend had a small amplifier that had originally been manufactured (illegally) for the CB market. Like most amplifiers of this type, the manu-



The front of the amplifier shows the power switch on the right and the LED power indicator on the left.



The rear view shows the placement of the SO-239 rf connectors and the power leads.

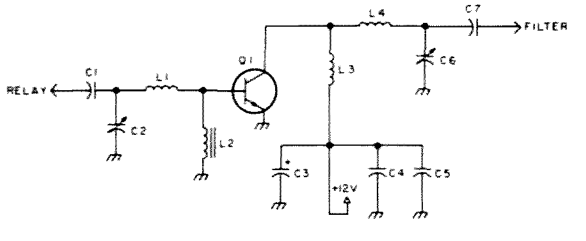


Fig. 2. Power amplifier.

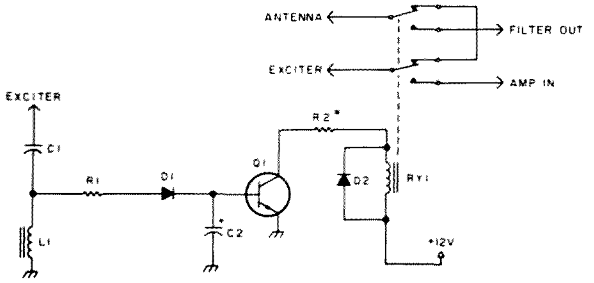

Fig. 3. Optional COR circuit.

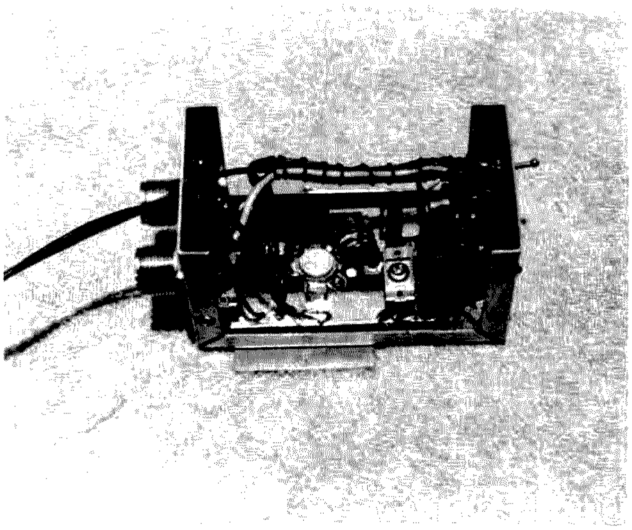

The first amplifier constructed did not have a heat sink as large as later units. The only heat sink used other than the enclosure was a small strip of aluminum used as a mounting bracket. This proved to work well when the amplifier was mounted on a metal automobile dash. The COR circuit board and relay are seen in the right end of the enclosure. The COR board was soldered to the amplifier board to facilitate mounting and conserve space. The enclosure shown in this photograph measures $2\frac{1}{4}" \times 2\frac{1}{2}" \times 4"$. In later versions, a larger enclosure was used.

facturer did not put his name or address on the unit so that no information was available on the circuitry. The only way to find out about the circuit was by drilling out the pop rivets holding the cover and looking inside. After much discussion, my friend agreed to let me take his amplifier apart.

Once the cover was removed, I saw that in its present state this was not what I was looking for. The circuit board was poorly laid out, the power transistor was not mounted on the board but was located on the side of the enclosure and had rather long lengths of wire running to the circuit board, and there was no output filtering.

The only redeeming factors for this amplifier were its simplicity and the availability of the parts used in it. It was definitely a junk-box project. The only part that I would have to buy would be the power transistor. With a new circuit board layout, perhaps some minor changes in component values, and output filtering, I should be able to produce a usable amplifier.

The input and output coils were each reduced by half a turn, L1 from $4\frac{1}{2}$ to 4 turns and L4 from $3\frac{1}{2}$ to 3 turns. The shank of a $\frac{5}{16}"$ drill bit was used as a form for each of these coils. They are wound of 16-gauge, solid-copper wire, either bare or enameled, and the spacing between turns is approximately equal to the diameter of the wire.

The collector choke, L3, was close-wound of 22-gauge hookup wire (enameled could be used). A $\frac{1}{4}"$ drill bit was used as a form for this coil. Input capacitor C1 was changed from 220 pF to 330 pF.

A new circuit board that would be easy to make and that would allow all of the

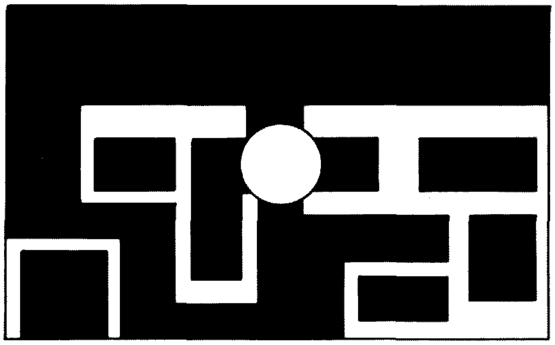

Fig. 4. Power amp PC board.

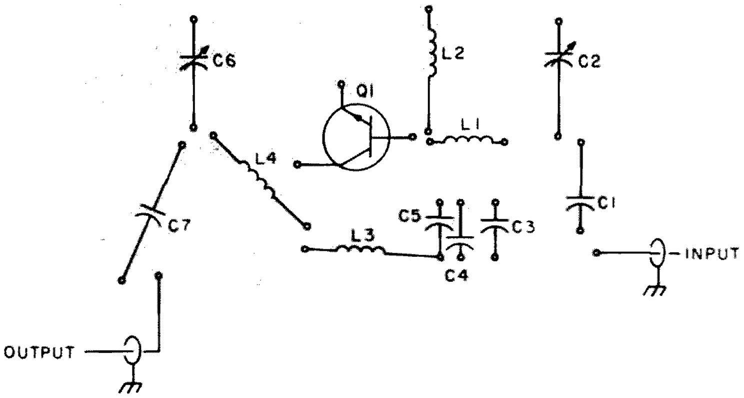

Fig. 5. Power amp parts placement.

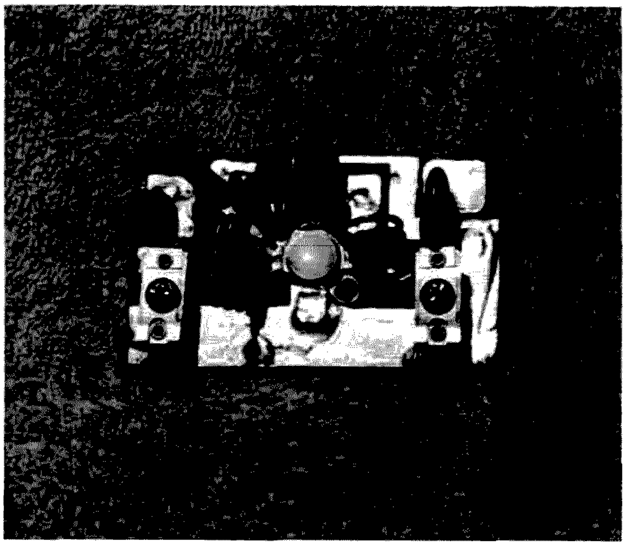

Circuit board of the first amplifier constructed. It used a flange-mounted power transistor rather than the stud-mounted MRF455A specified in the parts list. Later units used MRF455As because they only require a single round hole in the board, making them easier to mount. The input pad is at the upper left, the output at the upper right.

Parts List

Power Amplifier

C1	330 pF	NE*	$ .26

2 connectors (SO-239)	RS*	.99	
Enclosure, aluminum box, 5 1/4" x 3" x 2 1/8"	RS	2.49	
1 SPST switch	RS	1.99	
1 red LED indicator	RS	.79	(for 2)
1 series resistor for LED (use 470-Ohm resistor from COR)			

* NE—Newark Electronics, 500 N. Pulaski Rd., Chicago IL 60624; FS—Fuji-Seva, Box 3375, Torrance CA 90510; RS—Radio Shack.

components to be mounted on it was designed. I used 1/16" double-sided fiberglass circuit board with etching on one side and the foil left intact on the bottom. Components were soldered directly to the foil pads on top of the board. There is only one hole drilled, in the center of the board—the one for the power transistor. The power transistor mounts through the hole; its stud goes through the box used as an enclosure, and a 1/16" thick piece of aluminum was used as a heat sink. (The aluminum should be the same length and width as the enclosure.) Small spacers should be used between the circuit board and the enclosure to support the board. No strain should be placed on the transistor leads, and care should be exercised when tightening the nut on its mounting stud.

Tune-up of the amplifier is simple: Connect the exciter (3 or 4 Watts AM or CW) to the input of the amplifier and a 100-Watt power meter and a 50-Ohm dummy load to the output. Adjust trimmer capacitors C2 and C6 alternately for maximum power output. When maximum output is obtained, adjust C6 for approximately 50 Watts output. Compression or expansion of coils L1 and L3 may be necessary to obtain maximum output. A 12-volt power supply capable of supplying 5 to 6 Amps of current or a 12-volt battery should be used as a power source during this procedure.

The MRF455A is rated for 60 Watts when used with a finned heat sink, but neither the transistor nor the heat sink (the aluminum plate) gets warm during normal use. Care should be exercised during tune-up to keep the output near 50 Watts, or the transistor may possibly be overheated.

There are two ways of controlling the amplifier: by using a COR (carrier-operated relay) or by using the PTT line in your transceiver. If your transceiver uses relay switching, as mine does, it is a simple matter to run a control line from the PTT line to the amplifier-control relay. If you have electronic switching, the COR probably will be the easier way of controlling the amplifier; a schematic and circuit board layout are included with this article. The value of the electrolytic capacitor on the base of the switching transistor will have to be changed for use on SSB; 10 μF should be about right.

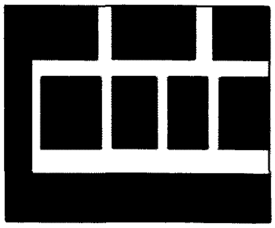

Fig. 6. COR PC board.

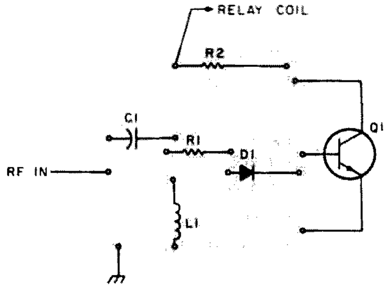

Fig. 7. COR parts placement.

Depending upon the relay used, the 200-Ohm resistor in series with the relay coil may be omitted or its value adjusted for positive switching (the relay in my amplifier would not drop out without the resistor).

A filter is needed on the output of the amplifier before putting it on the air. It may be an external filter or it may be built into the same enclosure that houses the amplifier. I used a tunable low-pass filter that I had bought at a hamfest. I tuned the filter for minimum interference on TV channel 2. (The filter has seven tunable sections.) I don't know how much this attenuates the second harmonic, but after tuning there was no interference to the TV receiver.

The amplifier is broadbanded and should work equally well on other bands. For this reason I have not included parts values for an output filter. Several suitable filters are discussed in chapter 15 of my *Radio Amateurs Handbook*.[1] Particularly interesting are the Chebyshev low-pass and the "Citation-Eliminator" filters on pages 15-7 and 15-8. I have not, as of yet, tried either of them.

The parts used in the construction of this amplifier are readily available. Mine, with the exception of the MRF455A, was built entirely out of parts that I had in my junk box. If all new parts are used, it can still be built for under $50.00. Parts sources and prices are given in the parts list. (If you shop around you can probably find lower prices.) I can supply etched and drilled PC boards for $7.50 and an SASE per pair.

I will try to answer any questions if they are accompanied by an SASE. ■

TVRO Troubleshooting

Get your Earth station off the ground with these signal-enhancing hints.

My head swells to twice its usual size every time I complete a home-brew project. After all, there is nothing quite like the feeling that accompanies turning a handful of parts into a living, breathing circuit. But then again, there is nothing worse than a project that *doesn't* work. My first experience with a satellite TV system taught me that. No need to worry about a swollen head; just give me a corner to hide in while I do the troubleshooting.

It's one thing if we are talking about a three-chip keyer that you have a grand total of $5.00 and two hours invested in. But watch out if the investment is in the thousands of dollars and hundreds of hours, not to mention promises made to family and friends. Perhaps the only thing worse than a TVRO system that shows no sign of working is a TVRO that puts out poor quality pictures. *"Is that the best it can do?"* the neighbors ask.

The problem isn't the satellites; it's just that getting a TVRO up and running isn't the same as taking a $2000 ham radio transceiver out of the box and making your first QSO ten minutes later. Troubleshooting is almost always called for. Even if you buy most of the components for TVRO, it takes some fine tuning. However, a dB here, a dB there, and pretty soon you'll have a picture that does justify a swollen head.

Gain Without Strain

You have to start somewhere, and unless you *know* what is wrong, I suggest you begin with the antenna. Backtrack a few steps and take a close look at the way your antenna is built. The gain of a parabolic dish is highly dependent on the accuracy of the surface. Most commercially-built antennas claim efficiencies between 50 and 60 percent, based on a surface accuracy where all errors are less than ± 1/16 of an inch.

You can't just give your antenna an eyeball diagnosis. A thorough checkup is in order, using either a carefully-made template or the mirror method described by Steve Gibson in the April, 1982, issue of *73*. The final check on your antenna's surface accuracy should be done while it is in operating position and subject to everyday stresses.

If the patient seems to be in danger, take preventive measures before proceeding. A one- or two-piece molded dish that is out of spec could spell disaster while antennas made from petals can sometimes be strong-armed into shape. But beware of a need for excessive pounding or bending. The whole surface should be accurate, not just one side! Luckily, commercial antennas have become much more reliable in recent months, but do check them carefully before you buy.

Photo A. Follow the crowd and point your antenna in the same general direction as everyone else. Be sure to include declination in your azimuth calculation.

If you home-brewed the antenna, then there is no one else to blame but yourself. Wood-frame dishes covered with window screen have become popular and they work well. Just make sure that each of the ribs is sanded down to match the master and that the screening is carefully applied. Bulges, ripples, and excessive overlapping will cost you gain. If you have built a spherical antenna (sometimes called an 8-ball or McCullough dish), spend an extra afternoon adjusting the tensioning bolts. Then erect the framework and recheck the curvature before installing the screen. This beats trying to smooth out the surface after it has been stapled into place.

Perfect Pointing

Once you are convinced that there is no way to squeeze another ounce of gain from the antenna surface, ask the question, is it pointed in the right direction? Don't laugh and turn the page. Photo A shows the value of going along with the crowd. But the chances are that you don't have twenty other satellite antennas in your backyard to use as references. Assume noth-

ing and go dig out the January, 1982, issue of *73*. On pages 60-62 is Steve Gibson's cookbook on satellite finding.

Follow the equations carefully. Better yet, have your ten-year-old work through the numbers. When you are done, assuming you live in the northern hemisphere, the bearing you arrive at should be somewhere on the southern horizon. Chances are it will be something like 238 degrees (New Hampshire) or 202 degrees (New Mexico). The elevation could be less than ten degrees if you live in the Arctic or as much as ninety if your QTH is on the equator.

The next step sounds simple but isn't. Is the dish pointing in the direction that the numbers say it should? You will need some sort of compass and inclinometer to find out and you must know the declination for your location. There are a hundred and one places to find the declination, or how far true north is from magnetic north. You can ask at the local airport, check a topographic map, or find a knowledgeable Boy Scout. The important thing is to include declination correctly in your antenna aiming.

Checking the elevation of the antenna isn't too tough. A protractor, along with a string and small weight, can be used. Or you can go whole hog and buy an inclinometer at the local hardware store (see Photo B). The method is up to you, but check and double check the azimuth and elevation of your antenna. Don't stay up nights worrying if you can't get the antenna perfectly aimed. After all, the compass and inclinometer have limited accuracy, so you'll need to do a little jiggling anyway to get the best picture.

We have been operating under the assumption that the only thing between your antenna and the satellites is a lot of air and maybe the occasional sea gull or pigeon. If the situation is otherwise, you may have built a nice piece of outdoor sculpture rather than a satellite dish! Buildings, trees, fences, and even a phone pole will absorb microwaves, so before you pour the concrete, make sure that the antenna has a clear shot at not just one bird but all across the satellite belt. The farther north you live, the more you will have to worry about obstructions, thanks to the decrease in antenna elevation angle that occurs as latitude increases.

Photo B. An inclinometer is helpful for determining the elevation of your antenna.

If a potential antenna site looks shaky, consider another location. Consider even a roof-mounted antenna as shown in Photo C. You can check a location by running a test with a portable antenna. This can confirm a clear path and tip you off about any problems that might result from earthbound microwave signals. But remember, even a field check can backfire. Consider the plight of one TVRO owner who shortly after installing a system found that his neighbor was building a garage that would stand directly in the signal's path! Like all other aspects of setting up a satellite terminal, site location must be done with care.

Feedhorn Fun

Assuming that the antenna is built right, located in a good spot, and aimed correctly, it is time to consider the next link in the TVRO chain, the feedhorn. Start by making sure that your feedhorn matches the antenna. Feedhorns are not created equal, and besides ending up with a downright poor one, you also could lose out if the horn over-illuminates the antenna (picking up unwanted ground noise) or under-illuminates the dish (which is the same as throwing part of the signal away). Perhaps the most popular horn for parabolic antennas is the scalar feed, sometimes called the Birkill, coaxial, or Chapparell feed. If you bought a budget-priced TVRO package, you may have the more traditional horn feed. In that case, it might be worthwhile to upgrade.

Besides matching the feed to the antenna, it is important to position the horn correctly, as shown in Photo D. If you don't, precious microwaves will be wasted. Find out what your antenna's focal length is and then measure out an equal distance along a line perpendicular to the center of the dish. The front edge of the feed should fall close to this point. Your feedhorn mount also deserves close attention. Not only must it be adjustable, but it also should be reasonably solid with no sagging. If you are using a home-built affair, avoid metallic or large supports that could degrade performance.

When the feedhorn is in its final position, it should point squarely at the center of the dish. If you have to point it to one side to get the maximum signal, it indicates that the dish surface is not right. As the feedhorn is adjusted, you should find one spot that gives the best signal. Any movement greater than ½ inch or so should cause the signal level to drop off. If you don't get a pronounced peak or if there are several peaks, then the dish needs attention.

Before giving the system a smoke test, it would be wise to check out the LNA. Is it attached securely to the horn with no gaps at the waveguide junction? Verify that the feedhorn/LNA combination is aligned for either horizontal or vertical polarity. If you are using a TV rotor, it might be best to leave it disconnected so that the horn can be twisted by

hand during the initial alignment. Or, if you want to go first class, consider replacing the rotor with a feed that has built-in polarity switching via a miniature motor or electronic rotation.

Make sure that the correct voltage is being supplied to the LNA. You may not be able to do this with LNAs that use the rf feedline to carry the power supply voltage, but no matter what kind of receiver or LNA you are using, don't scrimp on the cable that connects the two. Remember, you are not hooking up a CB radio. RG-58 won't hack it nor will hardline if you do a lousy job soldering the connector. By taking the time to do the job right, you'll reduce the possibility later of moisture ruining your signal.

D-Day

By now you are probably itching to make a smoke test. To make life easier, take the receiver (if it is an indoor type) and a TV set out to the antenna. This helps to avoid wild-goose chases that result from bad cable runs, and it makes it simple to observe the results of any adjustments you make. Before you throw the switch, double check all the connections. Don't be like one fellow who, in his excitement, forgot that he needed an rf modulator between the receiver and the TV set!

The next few steps are critical. To get the best possible picture, you'll need to adjust the antenna, feedhorn, and possibly the receiver. Although the adjustments don't usually interact, it is important that you deal with only one at a time, proceeding to the next step only after you complete the previous one.

Start with the antenna. If it has an az-el (azimuth-elevation) mount, leave the elevation setting alone and carefully vary the azimuth position. A swing of ten to fifteen degrees in either direction should yield a signal.

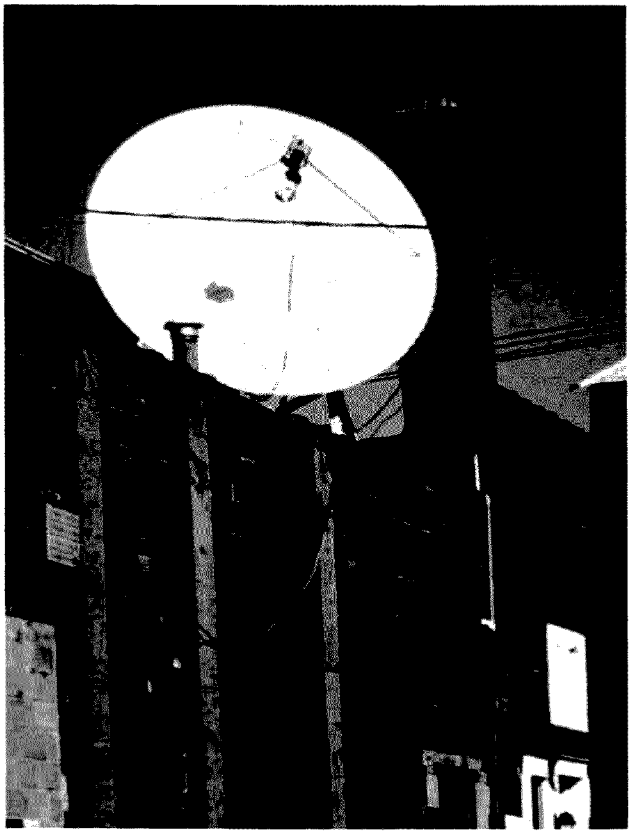

Photo C. If you can't find a suitable spot on the ground for your antenna, consider using a roof. It almost guarantees a clear shot at the satellites.

If it doesn't, recheck the elevation and original azimuth settings. If your antenna has a polar mount, it must be aligned against the north-south axis. Then you should be able to swing it through an arc without changing the elevation setting.

The first signal you receive may or may not be video. Don't be surprised if you get a jumbled screen and audio that sounds a bit like radioteletype or badly-mistuned sideband. All that you have to do is try another transponder on the same satellite or possibly readjust the antenna so that it points at one of the television birds. If you find yourself lost, return to the initial signal and verify that everything is still working.

Before you start scanning the sky in search of new satellites, it would be a good idea to get the feedhorn shipshape. All that should be necessary is a minor adjustment of its distance from the center of the dish and the polarity. Any substantial movement from side to side spells trouble. If you are using a spherical antenna, then proper placement of the feedhorn is crucial since it also determines the direction the antenna is pointing.

Peaking the signal requires that you have a steady source. Stick to one satellite and one transponder—preferably one that is transmitting color bars. The strength of such a signal will vary over time but will certainly be more reliably constant than signals from different transponders or, heaven forbid, different satellites.

Hopefully, your receiver has a signal-strength meter built in. Lacking that, there may be a terminal on the back for attaching an external meter. Or, as a last resort, you can use the screen as a reference. If you choose this route, it is imperative that the TV be located where the person making the adjustments can see it. Don't waste a lot of time making adjustments that you "think" are improving the picture. After all, there is a limit to anyone's ability to discern a change.

If you have gotten this far and made everything work, then you don't need any more advice from a magazine article. On the other hand, if you think you might be ready to forsake satellite TV for another hobby like stamp collecting, don't—at least not yet. For the time being, assume that the electronic part of the system is working. Concentrate your efforts on the antenna and feed. If your initial 20-degree sweep didn't work, make a slight change in the elevation setting and try another sweep. After a couple of tries at this, go back to the original azimuth and elevation settings and reposition the feedhorn. Repeat this sequence until you have systematically exhausted all reasonable positions.

Problems?

Still no luck? Then assume that something is wrong with the electronics. The best way to find the culprit is through the "buddy system." You need someone with a working TVRO who will let you try your receiver and LNA. Or, you could borrow their LNA and receiver to try with your antenna. This method of substitution is not terribly elegant, but it does work and sometimes is your only alternative when you lack test equipment.

Assuming that you have a commercially-built LNA, there is little that can be done besides verifying that it is hooked up correctly and the power supply is functioning. Manufacturers threaten to void the warran-

ty if you open up an LNA, and with good reason. There are no user-replaceable or -adjustable parts; all that you are likely to do is foul something up! Although receivers are not quite as touchy as LNAs, there is little that can be done to one if you don't have some sort of signal generator and a decent oscilloscope. Randomly tweaking the i-f cans with the hope that some miracle will occur is a sure invitation to disaster. The manufacturer may provide a few tips on what can or can't be adjusted by the user; as a last resort, you may want to give them a try.

Let's shift gears and look at some of the problems that you may have even though you are receiving pictures. The first problem is what satellite TV aficionados call "sparklies," otherwise known as snow. Sparklies are the result of noise that overpowers part of the signal.

The solution lies in boosting the level of the signal or reducing the amount of noise. The primary mechanisms are the antenna and the LNA. Is the antenna big enough? Is it providing the expected amount of gain? Does the LNA have a low enough noise figure? If you are convinced that your antenna is up to snuff, your only alternative may be a better LNA. Switch from a 120-degree unit to a 100-degree one. Obviously, this is an expensive fix and should be attempted only after you have tried everything else.

Adding another amplifier after the LNA probably won't help. By that stage, the noise is already present and a new amplifier will increase both it and the signal. A line amplifier could come in handy if you have a very long coax run between the LNA and receiver. This addition won't make up for a poor LNA or antenna, but it does ensure that the receiver has enough signal to work with. Line amplifiers also are used when one LNA drives several receivers.

Photo D. Feedhorn placement is critical. Start by finding your antenna's focal point and then make slight variations in the feedhorn position until the signal is maximized.

It may be hard to believe, but you can get too much gain. The result will be pictures that tear and smear. The solution is pretty simple: Just add some loss before the receiver. Loss can be had cheaply; a piece of coax should do the trick.

A TVRO can be likened to a chain and yes, this chain is only as strong as its weakest link! A good rule of thumb is that the first two links, your antenna and LNA, will have the biggest role in determining overall performance. Stephen Gibson's "Satellite Central" articles in the November and December, 1982, issues of *73* are well worth rereading if you are unsure of how strong each link must be. Remember that a combination that works well in one location may be less than optimal somewhere else. Satellite signals vary and receivers have special quirks. For example, a receiver with a PLL detector may be great for marginal signals but not so great for strong signals.

Another problem that you could encounter is drift. Frequent tweaking of the tuning dial might indicate an unstable oscillator stage. This problem is more apparent in single-conversion receivers but can plague double-conversion units, too. Pictures great but the audio is lousy or just not there? Remember that the audio is on an FM subcarrier and is processed separately from the video. The audio on most North American entertainment transponders uses a 6.2- or 6.8-MHz subcarrier. Is your receiver's audio control set correctly? Some services, like Music Television (MTV), may require special audio processing.

The final problem I'll address is probably the toughest to cure. You know that your TVRO is working because you are receiving some kind of signal. Unfortunately, this signal doesn't make any sense and you might receive it regardless of where your antenna is pointed. The culprit is terrestrial interference, land-based microwave signals that are in or near the 4.0-GHz TVRO band. As an unlicensed home-terminal owner, you pretty much have to grin and bear it.

Short of moving, there are two solutions, First, prevent signals from reaching your system. Use your LNA and receiver to sniff out the direction the offending signals are coming from and then locate your antenna so that something, let's say a house, stands between it and the signal source. If there is no way to completely shield the system, then you might try filtering out the interference. The success of this approach depends on the relative level of the interloper. You can avoid most terrestrial interference problems by doing a thorough site check and, when needed, using an antenna that doesn't pick up unwanted side or ground signals.

Building your own TVRO is not easy. Sure, you can take the easy way out and plunk down a bundle of cash and have a pro install a system for you. But thousands of hams have taken on the challenge themselves and succeeded. A smaller number of adventurous souls have built everything from scratch. A few relied on luck, but most learned the basics and paid attention to details. Learn from their experiences. Heed the fundamentals. Don't cut corners. Soon you'll have a working TVRO and a well-deserved swollen head. ■

Streamline the IC-25A

Add a dual-speed vfo and remote control. You can do it in a few easy steps.

Living within a mile of a local repeater, I had been experiencing a severe desense and cross-modulation problem with my "brand-X" rig when listening to other repeaters. The local repeater was annihilating the front end of brand-X. The ads for the new Icom IC-25A were very appealing, and I decided to try another radio as a solution to my problem.

One look at this mighty midget and my plastic money was on the counter, and the Icom was mine! If you haven't seen this little rig, you are in for a treat. It has all varieties of bells and whistles, and the design and craftsmanship are superior. It is so small (2"H × 5½"W × 7"D) that it suggests many convenient hiding places for a mobile installation. Furthermore, the desense problem experienced with my other rig was nonexistent in the Icom, even when parked beneath the antenna of the local repeater.

As with most rigs, we hams always want to change or add something, and the IC-25A was no exception. The two vfo's provided did not seem to give me any added flexibility; in fact, they created a difficulty. Using the 15-kHz vfo, I often would dial to some desired frequency and then find that I was either 5 kHz too high or 5 kHz too low. Then I would have to switch to the slow 5-kHz vfo and dial it to the desired frequency. This was frustrating and time consuming, so I decided to eliminate the dual-vfo feature and create a single, two-speed vfo.

Another convenience I wanted was a remote scanning control. The IC-HM8 touchtone™ microphone supplied with the IC-25A did not have this feature, so I decided to add it to the mike.

Memory retention was another item considered, but the thought was abandoned when I could not find space to mount a battery inside this very compact transceiver. Furthermore, I learned that Icom has available a memory-holding device identified as BU-1 which fits between the two halves of the external power connector.

You will find that the following changes make an excellent little rig even bet-

Photo A. New scanning switch installed.

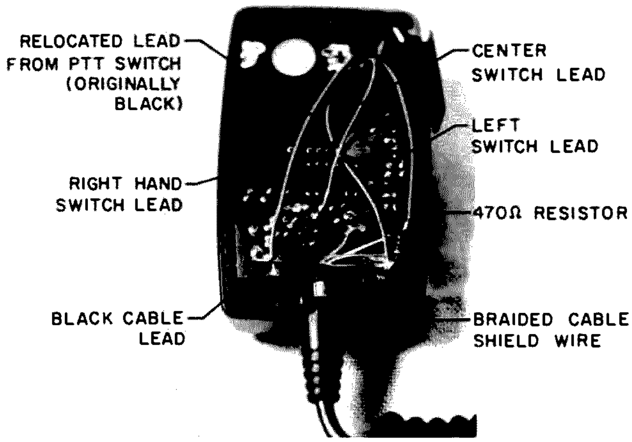

Photo B. The scanning switch wiring.

ter! In performing the modifications, the technician should refer to the comprehensive schematics and pictorials furnished with the IC-25A.

For convenience and selection, these modifications are identified separately as Mod A, B, and C. It is suggested that you read all three mod instructions before proceeding, to help you decide which ones you may want to accomplish. These changes are not difficult, but they do require some expertise in working on solid-state circuitry and printed circuit boards. Therefore, this work should *not* be attempted by "first timers."

Mod A

This modification converts the dual vfo to a single vfo with two-speed control. Also, the existing fast-speed dial rate is changed from 15 kHz to 25 kHz. The original vfo push-switch now becomes a slow/fast dial rate selector. It also functions to change the rate during the full-range-scan mode.

1) Remove the top and bottom covers of the IC-25A. When removing the lower cover, unplug the speaker from the mating plug on the PC board.

2) Remove the four front-panel knob controls (Vfo/Memories, Main Tuning, Volume, Squelch). All knobs will pull off their shafts. The large tuning knob may be tight and may require gentle, simultaneous prying underneath two opposite sides. Use two table knives with pieces of cardboard underneath them to protect the face of the panel. Pry up evenly.

3) Remove the two top screws and two bottom screws and carefully slide off the front, black bezel (panel).

4) Remove the two screws on the left side and two screws on the right side that hold the front control assembly to the main chassis.

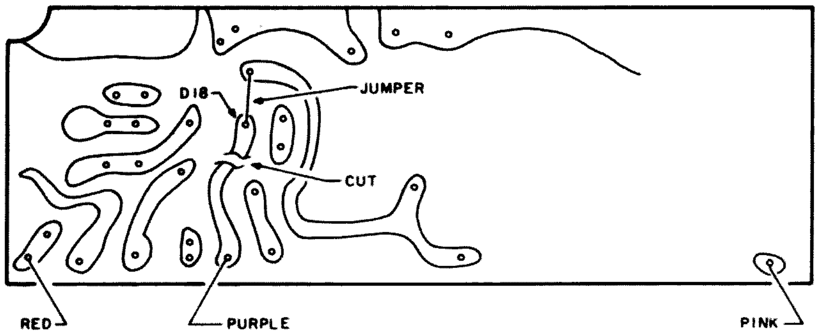

Fig. 1. Switch board, foil side.

5) Carefully move the front control assembly forward to separate it from the main chassis.

6) Take off the retaining nuts and remove the volume and squelch controls from the front control assembly. Place them carefully aside. It may be necessary to free their wiring from the harness assembly by cutting a wire-wrap.

7) With the unit and front control assembly upside down, locate the switch board assembly. It is a small PC board situated directly behind the three push-switches (Scan, Simplex, Norm).

8) Refer to Fig. 1 and locate the *red* wire at the extreme *left* corner of the switch board. Unsolder this lead and lengthen it by splicing a 1½" piece of wire to it. Solder the end of this extension to the *pink* wire located at the extreme *right* corner of the switch board. This wire relocation creates the single vfo with the original tuning rates of 5 and 15 kHz.

9) Refer to Fig. 1 and locate the *purple* wire on the edge of the switch board. From this connection point, follow the board foil up to its end where there is a single soldered connection. This connection is the cathode end of diode D18. Using an X-acto® knife (or other sharp blade), very carefully cut across the foil below this point. This action disconnects D18 from the purple wire. Check with an ohmmeter between the purple wire and the D18 solder point to make sure that you have completely severed the connection.

10) Using a small bare wire, solder a short jumper from the isolated connection point of D18 to the board foil directly *above* it, as shown in Fig. 1. Be careful not to bridge any solder to adjacent areas. This action converts diode D18 to a new function as D32 and creates the faster dialing rate of 25 kHz.

11) Carefully replace the volume and squelch controls in their original positions with their locating tabs in the proper holes. Secure them with the original nuts.

12) Reattach the front control assembly to the main chassis with the original four screws.

13) Reassemble the panel bezel on the front control assembly with the original four screws, and press all four knobs back in their proper place.

14) Take the bottom cover and plug the speaker lead back in place with its mating connector on the PC board. Observe the plug polarity. Place top and bottom covers in place and secure with original screws.

After this work is completed, you will have a single vfo with the A-B vfo push-switch now functioning to change from a slow to a fast tuning rate (5 or 25 kHz). The yellow light above the switch will now stay lit at all times.

Mod B

If it is desired to create the single vfo but maintain the original tuning rates of 5 and 15 kHz, then perform Mod A but do only steps 1, 4, 5, 7, 8, 12, and 14. After this work is performed, you will have a single vfo with the A-B vfo push-switch now functioning to change from a slow to a fast tuning rate (5 or 15 kHz).

Mod C

This mod is to install an UP-DOWN scanning-control switch on the IC-HM8 microphone.

1) Obtain a subminiature SPDT toggle switch, *center OFF*, momentary contact (Calrad P/N 40-584 or equivalent).

2) Remove the single screw and take the back cover off the microphone.

3) Gripping the PC board at its edges, carefully lift it upward. This will unplug it and separate it from the mating plug on the tone pad. While still connected, lay the PC board aside exposing the inside of the mike case.

4) There is an oval hole existing in the case directly below the microphone element location. Carefully drill a ¼" hole through the center of this oval. It is best to drill a pilot hole with a small drill (i.e., 1/16") and enlarge the hole slowly by increasing sizes to ¼". Make the pilot hole from the inside out, but enlarge the hole from the outside in. This will prevent pushing and loosening of the front panel.

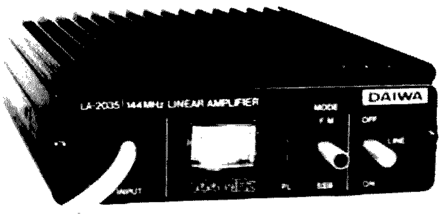
5) Remove all hardware from the switch shaft and install it in this hole. It will be necessary to fabricate one

CROSS NEEDLE METER
DAIWA

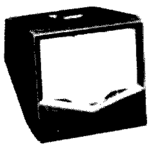
BE HEARD! GIVE YOUR HAND-HELD THE BOOST IT NEEDS!

The New Daiwa LA-2035 two meter linear amplifier.
A compact amp at a compact price
Only $79.95 Suggested Retail.

This amplifier is designed for use with hand-held transceivers in either mobile or fixed station configurations.
Because of its light weight and compact size, the LA-2035 can be mounted under the dash, under the seat, or in any other convenient location.
The LA-2035 is equipped with RF activated stand by circuitry.
Easy operation. Simply connect your antenna and your hand-held to the LA-2035. Connect the LA-2035 to a suitable power supply and go.



Specifications
Band: 144-148 MHz
Mode: FM/CW/SSB
Input power: 1-3 watts
Maximum output power: 30 watts plus.
Power consumption: 13.8VDC at 5A Max
Dimensions: 100W × 35H × 125Dm/m
Weight: 500 grams
Coaxial input cable supplied with a BNC connector.
Output connector: SO239



CN-520/CN-540/CN-550
Cross Needle Meters
Daiwa cross-needle convenience in a compact case
Get SWR and Power readings in a single glance

Exclusive U.S. Agents for these DAIWA products. Dealer inquiry invited.

or two spacing washers to provide a flat contact for the nut. Use a ¼" washer and cut or grind off one edge up to the edge of the ¼" hole. Secure the switch with a nut (refer to Photo A).

6) Cut three 5" lengths of #22 wire and solder one to each of the three switch terminals. Place these wires so that they protrude from the top of the mike, and then plug the PC board back in position.

7) Unsolder the black lead from the PTT switch where it connects to another black lead from the cord at the bottom of the PC board. Connect this black lead to the same ground point on the PC board as the braided shield wire from the cable.

8) Take the center wire from the new switch and connect it to the same point where the black PTT wire was just removed. This connects it to the black cable wire.

9) Take the left-hand switch lead and connect it through a 470-Ohm resistor to the ground foil on the PC board.

10) Take the right-hand switch lead and connect it *directly* to ground on the PC board. (See Photo B for connections.)

11) Replace the back cover and secure with the screw.

12) Open the connector on the other end of the cable, unsolder the black lead from lug 6, and resolder it to lug 3.

13) Reassemble the plug.

This completes the modification and you now have UP-DOWN scan control from your microphone. This feature does not affect the normal operation of the S/S scan switch on the front panel of the IC-25A. If desired, the length of the plastic bat handle on the new switch may be cut to a shorter length. ■

A Perfect Match for the HW-8

Heath's little rig is the QRPer's dream come true. So is 30 meters. Join them with this super-fast mod.

On October 28, 1982, the Federal Communications Commission opened up most of 30 meters to US amateurs. Those of us with newer rigs were able to get on the air by adding a new dipole to the antenna farm or by finding a new tap on the antenna tuner coil. However, most of us with older rigs were faced with the possibility of having to wait until we could get a newer rig. Many older rigs, like the Heath SB/HW series, would be a little difficult to modify.

QRP operators, though, are fortunate to have the much-modified HW-8 to play with. The purpose of this article is to describe a simple modification to allow you to convert your HW-8 to 30 meters with a crystal and three capacitors.

The HW-8 is a direct-conversion receiver which generates the local oscillator signal by mixing a crystal oscillator and a variable-frequency oscillator. This allows the vfo to run at one frequency and facilitates multiband operation. This same system allows easy conversion to other bands.

In order to convert the HW-8 to 30 meters, all you need to do is change one of the crystals and realign the rig. I suggest that you change the 20-meter crystal. It appears to be easier to move the rf circuits at 20 meters down to 30 meters than it would be to move the 40-meter circuits up. In addition, the transmitter PA-output network is a low-pass filter, and moving the 40-meter low-pass up might require major surgery. This modification requires no surgery at all—only a few additions.

Once you gather the parts together, the entire conversion should not take you very long. Following are step-by-step instructions covering the conversion and realignment:

1. Referring to the Heathkit™ HW-8 circuit diagram, remove both covers, unsolder the 20-meter crystal, Y3, and replace it with the 30-meter crystal at 18.895 MHz.

2. Locate L19 and C121. Solder a 30-pF capacitor across L19 in parallel with C121. It is easiest to tack this new capacitor on the bottom of the circuit board. This facilitates reversal of the modification.

3. Locate C7 and C22 in the rf amplifier circuit. Add 60 pF of capacitance in parallel with each capacitor. I used two 30-pF capacitors across C7 and C22 each. Anything in the 60-pF range should work as well.

4. Replace the bottom cover. This completes the modification; only alignment is left.

5. Attach an rf probe and VTVM to the base of Q7. If you don't have an rf probe, use the circuit Heath suggests in Fig. 1. Adjust L19 for maximum response on the VTVM and then turn the coil slug ¼ turn counterclockwise. L19 is the *bottom* slug in the L19/L21 coil can.

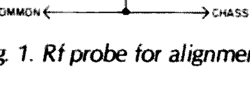

Fig. 1. Rf probe for alignment.

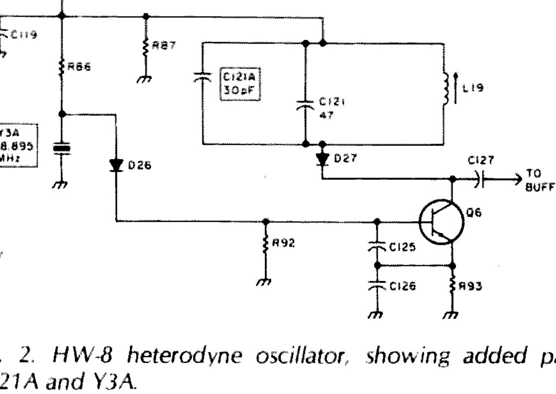

Fig. 2. HW-8 heterodyne oscillator, showing added parts C121A and Y3A.

6. Move the rf probe to the emitter of Q5. Adjust L15 for maximum response. You will have to move the coil slug almost to the bottom.

7. While listening to an on-the-air signal (WWV is convenient), adjust C7 and C22 for maximum received-signal strength.

8. Attach a 50-Ohm dummy load to the output, key the transmitter, and adjust C103 (in the final amplifier) for maximum output with the loading control at the 12-o'clock position.

9. If you want, you can calibrate the vfo using WWV at 10 MHz. Put the top cover back on.

10. Have your first QRP QSO on 30 meters.

The results are excellent. My HW-8 has a 30-meter power output of 1.2 Watts into a 50-Ohm load. Within two minutes after finishing the realignment, I worked NN4F in Memphis. He gave me a 579. I find that I can work stations on 30 meters easier than I can on 20 while using QRP. There is some high-power teletype on the band, but you can sneak around that.

The receiver performs fine although I have not been able to evaluate it for sensitivity and dynamic range. The converted HW-8 seems to work just as well on 30 meters as it does on any other band!

So there you have it; a thirty-minute modification to put you QRP on thirty meters. Come on down to 10.1 MHz and have some fun! ■

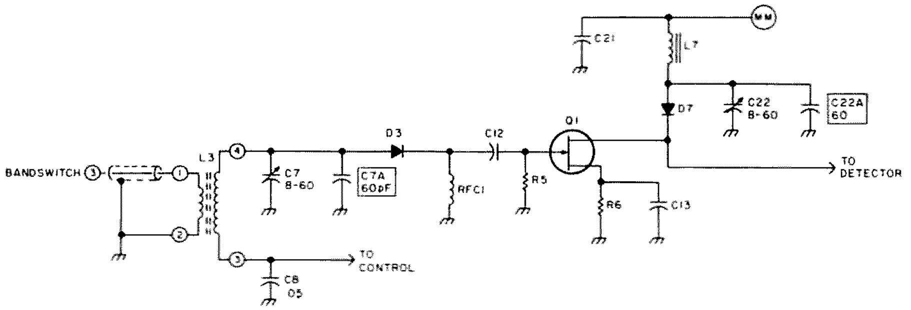

Fig. 3. HW-8 rf amp showing added capacitors C7A and C22A.

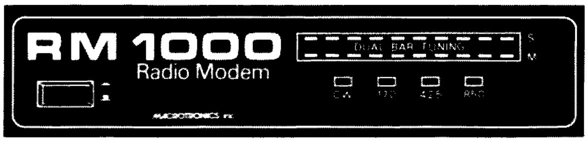
Parts List

Y3A	18.895-MHz crystal, type OF-L, cat. no. 031300, International Crystal Mfg. Co., Inc., 10 North Lee, Oklahoma City OK 73102. Price: $6.88.
C7A, C22A	60-pF capacitor, Radio Shack, Jameco, and other suppliers. Value of 50 pF to 70 pF acceptable.
C121A	30-pF capacitor, Radio Shack, Jameco, and other suppliers.

Capacitor values may be approximate and determined experimentally. I used 30-pF capacitors from a Radio Shack assortment, paralleling two to get 60 pF.

NEW

RM 1000
Radio Modem



apple • ATARI • IBM • TRS-80

The RM 1000 is a modem which allows your microcomputer to send and receive Morse Code and RTTY over radio.

Unquestionably the finest radio interface available today at any price. Easy to connect. Easy to use. Very competitively priced. An unprecedented value!

Commercial quality hardware copies the weakest of signals. Unique Dual Bar Tuning™affords instant, accurate tuning Morse and RTTY signals.

Thousands of satisfied customers can attest to the superiority of Macrotronics software. Easy to use. Error free. More features. Outstanding documentation.

HARDWARE FEATURES

* Commercial quality demod filters.
* Crystal controlled AFSK tones.
* Dual Bar Tuning™-accurate & easy!
* 110/220 AC power supply included.
* Shifts/Modes under keyboard control.
* Convenient rear panel connectors.
* 15 Day money back trial period.

SOFTWARE FEATURES

* CW, Baudot, ASCII send/receive
* Multi level split screen with Review Window
* Four user definable WRU's (keyword auto response system)
* 16 user defined messages are dynamically allocated & linkable
* Word wrap, diddles, auto unshift, UT4, auto ID, disk I/O and more!

Don Wallace: Superham

Meet W6AM, the Grand Old Man of amateur radio.

Author's note: Some of the material in this article was written by Peter K. Von Hagen WA6HXM. The author extends his gratitude to Mr. Von Hagen and also to *The Palos Peninsula News* for permission to reprint excerpts from his well-written article.

How many hams do you know who have been the personal radio operator for a US President, won the Hoover Cup for having the best amateur station in the nation, been the world's champion DXer for many years, and have mobile rigs in their automobiles operating with one kilowatt of power on the low bands and 250 Watts on two meters?

There is only one person among the hundreds of thousands of amateur radio operators in the world who meets the qualifications listed above, and many of you have probably already guessed his name and call: Don C. Wallace W6AM—the 85 years young Grand Old Man of Amateur Radio.

Early Years

Wallace was born in 1898 in Belview, Minnesota (current population: 439), where his father was a banker. The transfer of his father to another branch of the same bank in nearby and considerably larger Redwood Falls represented a step up the ladder, so the family moved there. In 1905, they moved to Los Angeles, where the population at that time was only one hundred thousand!

In 1908, Don began to peruse his father's physics books. He found out how doorbells, motors, etc., worked and, putting his new knowledge to immediate use, actually constructed a motor, a doorbell buzzer, a telegraph sounder, and a key.

Two years later, Don and his friend John Cook used number 18 rubber-covered wire to construct a five-block-long telegraph line between their homes. The line was fastened to telephone company poles for the four blocks before the tracks of the Pacific Electric Railway were encountered. Fortunately, the railroad had two poles very close together at that particular location, one on each side of the track. This facilitated running the wire under the rails to Cook's home a block further on.

This line furnished a lot of code practice and also served as an excellent antenna for Don's first crystal set until the wire running under the tracks was discovered by a railroad worker who, not knowing what his eventual destination would be, started coiling it up and finally delivered a very large coil of wire to the Wallace residence.

Don Wallace was a youngster with a huge curiosity. In those days, number 6 dry cells were used in a "make and break" circuit to produce square wave ac which could, of course, be stepped up to many thousands of volts to provide ignition voltage for the automobiles of that early age.

Don's uncle in Anaheim, California, with whom Don was visiting, had considerable trouble in starting his automobile due to weak batteries, so a trip was made to a nearby garage, and Don went along. Don asked the mechanic what he did with the old batteries, and the man pointed to a large pile of discarded cells in a back corner of the garage and told Don to help himself. He loaded about one hundred dry cells into his uncle's vehicle and hauled them to Anaheim. At a dime store, he bought a roll of copper wire for ten cents. He connected all the dry cells in series and was able to produce a good spark, thus introducing himself to the world of spark communication.

Upon his return to his Long Beach home, Don strung a length of copper wire to a neighbor's home and they began communicating in code. Another neighbor showed Don a 20,000-volt transformer with a spark gap that he was using. This neighbor had a cat that would sit right on the spark during transmissions, barely moving when the 20,000 volts was applied. Watching that operation convinced Don that cats have substantially more than nine lives.

Don's next step was to visit the man who installed stove pipes in Long Beach. That gentleman allowed Don the use of his machinery to cut stove pipes into appropriate lengths to serve as transformer cores. Don then spent the next two months winding his own 20,000-volt transformer. A crank arrangement was built into an apple box which made the winding of the wire around the transformer cores easier. Paraffined paper was placed between the layers of wire.

After completion of the transformer project, Don built a simple homemade receiver. (There was, of course, no source of commercially-made receivers at the time.)

The Bureau of Navigation of the US Department of Commerce had not, in the infant state of radio at that time, arranged examinations for persons to qualify as radio operators, so Don wrote, "I can send and receive five words per minute in code. [Signed] Don C. Wallace." He had the statement notarized for a fee of 25 cents and mailed it to the proper authorities and soon received the call 6OC. John Cook received 6OD, and they went on the air immediately.

John Mead, a buddy of Don's in neighboring Hollywood, was licensed as 6OE in 1912. His rotary spark-gap transmitter had a very high-pitched note, while Don's 6OC station had a medium-pitched note. Everyone tried to have a distinctive note to his signal with the result that it was often possible to recognize a station merely by its "note" even before it officially identified itself.

Don and Mead had switches which would turn the motor driving the rotary spark gap on and off without turning off their transmitters. While this motor was building up speed when it was first turned on or when it was losing speed after being purposely turned off with the transmitter in operation, it would change the pitch of the transmitted signal very significantly; Don can imitate perfectly those variations in signal note even to this day.

At that time, Don constructed an automatic identifier for his station, utilizing a wooden wheel, using brass-headed upholstery tacks and strips of brass on the outer circumference of the wheel to form the dots and dashes, respectively, which were necessary to transmit the call 6OC.

Don is shown here in Minnesota in 1924 holding the Hoover Cup which was awarded him by the US Department of Commerce for having the best amateur radio station in the United States during the previous year.

Maritime Operation

PJ, the Marconi Wireless Company station only six miles away in San Pedro, was annoyed with Don for causing interference to commercial traffic. (That station's call letters were soon changed to KPJ to indicate its commercial status.) But KPJ was Don's idol. He rode his bike to the station one day and introduced himself to the station manager, who told him that he would get Don a position as a ship wireless operator providing Don could obtain a commercial operator's license.

All the radio operators' exams were administered in San Francisco, so Don went down to the harbor and talked with the officers of several ships then in port. At six feet, four inches, Don (at age 15) convinced one officer that he could clean the overheads (ceilings) of the ship's rooms without using a ladder, an important point to the ship's owners since using a ladder in a rolling sea was considered a hazardous procedure to be avoided if possible.

Don was "signed on" as an able-bodied seaman aboard the S. S. *Yale*, a passenger ship bound for San Francisco. There he passed the Second Class operator's examination. Just as today, one could not obtain a First Class Radiotelegraph license without shipboard experience.

Returning to Long Beach, he again visited KPJ where he heard one of the ship operators complaining that he would much rather go to the baseball game than work his shift. Alertly, Don told the Chief Engineer that he could handle the job. The Chief agreed and Don was paid the sum of one dollar.

Incidentally, Poly High School had its own spark station, with a block-long antenna suspended between two 80-foot towers. Guess who was largely responsible for the school having such an installation. Hint: Don Wallace has always been an advocate of *long* and *high* antennas.

Shortly after his experience as a substitute KPJ operator, Don was assigned to one of the Banning Brothers ships operating between Long Beach and Catalina Island. Although it had a rated capacity of 1,000 passengers, the load on the return trips from the island on Sunday evenings and on holiday evenings was more likely to be 2,000 persons. On return voyages, a message had to be transmitted to Long Beach Harbor advising the passenger count and how many passengers wished to use the "Big Red Cars" so that the Pacific Electric Railway would have the proper number of streetcars on hand. It was also mandatory to provide information as to how many passengers wanted taxis. Don handled this traffic without a hitch.

More important than the pay was the fact that he could now claim experience as a commercial operator. Once again Don "overhead-washed" his passage to San Francisco and passed his First Class Radiotelegraph operator's exam with a grade of 99.4 percent.

From that point on, during all vacations from high school, Don signed on as radio operator for ships sailing up and down the Pacific coast, some of which went a considerable distance up the Inside Passage north of Vancouver, B.C., to be completely loaded with cargos of lumber. Don found that he also could work as a longshoreman while the ship was in ports. As a high-school football player, Don wanted to gain more strength, so he would load and unload the ships whenever possible.

Speaking of football players, Don says antennas are like football players: A good big one is better than a good small one.

After graduating from Poly High in 1916, Don entered Hamline University in St. Paul, Minnesota, to study banking and business. His fascination with amateur radio remained as strong as ever, and shortly after his arrival on campus he obtained the permission of the college president to install a ham station. The "Old Main" administration building had a steeple 130 feet high. Don added a 40-foot pole and attached one end of his main antenna. The other end was attached to a church steeple two blocks away. Another antenna extended to the Ladies Hall, a block away, and still another ran to the university library, a mere half-block away. The results from this station were excellent, and Don soon became well known in the Midwest as the "Big Signal," a reputation he has never relinquished.

World War

When the United States

became involved in World War I, Don's friends rushed to join the Army, but Don's allegiance was more to the Navy since he had enjoyed his seagoing adventures. It was announced that Navy recruits living on the west side of the Mississippi River would be assigned to the West Coast, so instead of going to the St. Paul recruiting office, Don journeyed a few miles to Minneapolis on the west side of the river to the Navy recruiting office there. He was told to finish his first year of college so he could be given the rank of Second Class Petty Officer. So it was that after leaving Hamline he was immediately assigned to NPG in San Francisco, the main Navy radio station serving the Pacific Ocean. At that time, it was equipped with 300-kW arc transmitters and 600-foot towers.

Don arrived at NPG and the personnel officer told him to go into the operations room and observe the actions of the First Class Petty Officer who would show him what to do. After an hour of operations, the duty officer said that with an additional hour of instruction in Navy procedures, Don would be ready to operate the station. His code speed had already reached 35 wpm in both the International Morse code and the American Morse code, so when the famous "pink ticket" radio operator licenses became available (providing you could copy without error 30 wpm in International and 25 wpm in American code), he passed the examination without difficulty.

Readers may wonder why some individuals developed expertise in both codes. Part of the explanation for this was that until about 1908 or so, American Morse was the only code in use. When wireless came into existence, operators had to learn International Morse if they wanted to participate in the new method of communications. Thus, they became expert in both codes.

This photo shows Don's home in Long Beach in 1936 after he had been up all night transmitting pictures to Chicago of the floods and slides which had occurred in the Los Angeles area. Telegraph and telephone lines were inoperative due to the disaster, so amateur radio came to the rescue once again.

Another factor that increased the number of operators skilled in both codes was that shore stations owned by commercial radio companies such as Marconi Wireless and Radio Marine usually had a "pony wire" using American Morse operating from the station to the downtown Western Union office. Expertise in both codes was required to hold one of these shore station jobs. Even today, Don is equally expert in both codes and uses a special microswitch on his Palomar keyer to send the long dash representing the letter L in American Morse.

Don had a number of interesting experiences while assigned to NPG. On one occasion, the personnel officer reported that he hadn't heard from the lightship stationed 15 miles out from San Francisco Bay for more than a month. Don told him there wasn't a radio ever made that couldn't be repaired and suggested that he be assigned to make the repairs. He was sent out to the lightship on the next supply tug and had the repairs completed in about 90 minutes. When he requested permission to return to shore with the tug, it was denied and he was ordered to remain aboard the lightship for another two weeks.

He used that time to put the ship's five-kilowatt transmitter and all the receiving equipment into first-class condition. Then, noticing that there were no instruction books or manuals for the radio equipment aboard the vessel, he typed a 75-page booklet with service instructions and diagrams. Leaving a copy aboard, he brought the carbon copy of the booklet ashore and turned it over to the personnel officer to be used in case the original was misplaced.

After a quick visit to the Admiral's office, the personnel officer returned to inform Don of his promotion to permanent-grade Chief Petty Officer. He was 19 then and couldn't become a commissioned officer because he was less than 21 years of age.

Submarines and The President

Don next volunteered for submarine service where he served eight months. The "submarine-qualified" notation on his record added considerably to his Navy paycheck, but at six feet four inches he was just too tall to serve comfortably aboard submarines with their limited overhead clearances. He wanted to return to college as the war wound down, so he requested transfer from the submarine service to a receiver ship and was assigned to the Brooklyn Navy Yard.

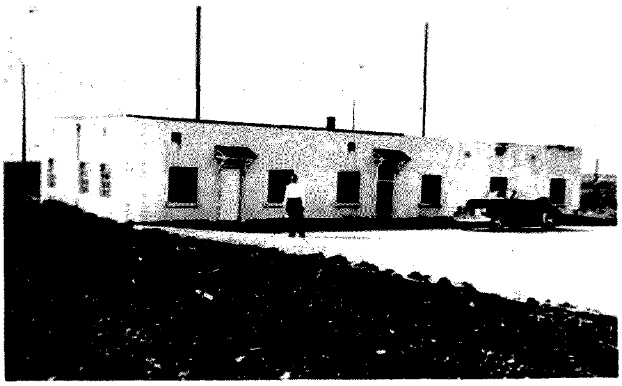
An officer there remembered Don's skill as an operator and asked if he knew anything about arc transmitters. He said the Navy was installing a 40-kW transmitter on the Presidential yacht, the *USS George Washington* (which was quite a "yacht" since it was 800 feet long), for President Wilson's use to and from the Peace Conference at Versailles. Apparently, none of the radio operators knew anything about the new transmitters, but Don did, since he had operated

and maintained similar equipment on the West Coast where arcs had been developed. Immediately he was put in charge of the radio operation aboard the *George Washington* and he accepted the appointment as Chief Radio Operator for the President of the United States after being persuaded to delay his return to college for a few months.

Don and the 35 operators under his command never missed a schedule with the new equipment. (Among them, incidentally, were Fred Schnell of ARRL fame and Harold Beverage, inventor of the Beverage wire antenna.) Shortly after President Wilson came on board for the trip to France, Don had established 40-kW radiotelephone contact with the Secretary of War, Newton Baker. On his arrival in the radio room to talk with Baker, President Wilson developed a bad case of mike fright and was unable to talk on the air. Don proceeded to talk with Mr. Baker for a few minutes until the President recovered his composure and was able to talk. Can anyone today imagine a President being afraid of a microphone? (After that, the President spent much of his spare time in the radio room.)

In addition to his radio duties, Don was an avid photographer, and he took hundreds of photographs during the trip. In subsequent articles about World War I and President Wilson, many of the photographs published were those taken by Don.

After the first day of negotiations at the Versailles Peace Treaty Conference, messages concerning it were dispatched by President Wilson back to the United States, using the facilities of a French 1,000-kW arc station at Lyon. However, mistakes were made in those first day's messages, so from the second day on, couriers with locked briefcases handcuffed to their wrists traveled between Versailles and Brest to transport all radio communications to and from the radio room of the *George Washington*. Completing his six-month mission aboard the *George Washington*, Don decided it was time, at last, to return to college.



Don poses here in 1945 at the entrance of the former receiving station of Press Wireless. Eight commercial radio operators operated 75 receivers daily here to bring the latest news to the Los Angeles Times, *while eight more operators labored at the transmitting facilities of the same firm in nearby Marina Del Rey. Don purchased this building and more than one hundred acres of land from Press Wireless in 1944 and has transformed this boxlike structure into an attractive ham shack with the addition of a peaked roof, landscaping, and porches on both sides of the building.*

The Twenties

Don Wallace returned to Hamline—and its football team, which became Northwest champions. He remained in the Naval Reserve since the annual pay was equal to two months of active-duty salary. Transferring to the University of Minnesota after two years at Hamline, he continued to play football on the university's team.

On the faculty there was C. M. Jansky, one of the greatest professors of radio of the time. Since Don was permitted to choose 20 percent elective courses not related to his business major, he decided to enroll in all of Jansky's classes.

The professor was elated to have an experienced radio man in his classes and soon assigned Don to duty at the university's broadcasting station and fine ham station every Wednesday evening. A different student was assigned with him each time and they would stay on the air all night, with Don filling the roles of Chief Engineer, MC, announcer, and program director. He would do live interviews with dignitaries such as the governor of the state, congressmen, and the president of the university. The guests would talk for ten minutes, and then Don played records or commented on the news. This was the first regular broadcasting in the northwest.

When the author of this article began hamming in 1930 in a remote corner of North Dakota, the achievements of Don Wallace were already legendary. Indeed, the November, 1924, issue of *QST* saluted him in a full-page article entitled "Who's Who in Amateur Wireless."

Calls held by Don in Minnesota included 9BU, 9DR, and 9ZT. Next, the Federal Radio Commission issued him 9XAX, which authorized him to operate on any frequency, any time, with any power. The FRC knew it could trust Don not to abuse the carte blanche privileges of such a license.

In 1923, Don was awarded the Hoover Cup for having the best amateur radio station in the United States. (There's no need to worry about the silver plating peeling off the cup with the passage of half a century. There is no plating to peel; the cup is constructed from a solid piece of silver.) When Herbert Hoover became President, the amateur radio signal of W6ZH operated by the late Herbert Hoover, Jr., from the White House, reached westward and sought out and found, on many Tuesdays, the long and high antenna of Don's W6AM.

Don had a part in the original bridging of the Atlantic Ocean by Fred Schnell and John Reinartz. Don's station, then located in the 9th district, was the furthest station worked by Leon DeLoy F8AB.

While Don was still at the University of Minnesota, the General Electric Company let it be known that they wanted a graduate to manage their radio department in Minneapolis. Don took the job and in six months was making more money than the president of the company. Don held that job with General Electric for 4½ years. Among the products he sold were those of the National Radio Company. When National's sales manager, George Hill, offered Don a position covering California and eleven other western states, Don accepted in 30 seconds. The Wallace family moved back to Long Beach, and Don wired his resignation to General Electric.

Also while at Minnesota, Don met Ed Johnson, a mechanical engineering student. Upon graduation, Ed started the E. F. Johnson Company to manufacture radio parts at Waseca, Minnesota. That company be-

came a very well-known supplier of amateur radio components and transmitters and is still in business today. (It has sold its patents and dies for the manufacture of telegraph sounders and keys to the Nye Company, which still does a brisk business in such items.) Don suggested the original designs of about half of the products that the E. F. Johnson Company manufactured.

When Don came to the West Coast in 1926 to represent the National Radio Company, he wrote to Ed that he would like also to represent the E. F. Johnson Company in the west. Johnson replied that manufacturers' representatives were a "bunch of bums" and that he didn't need a representative to sell his products. Don wrote up a dozen large orders and sent them to Ed with a note that these orders were for old times' sake and their friendship. Johnson filled the orders and sent Don a commission check. Don kept sending orders and Ed kept paying commissions. It wasn't long before Don had the territory officially and on an exclusive basis.

At the height of his career as a manufacturer's rep, Don represented a total of 19 manufacturers of electronic equipment. One account alone brought in a *monthly* commission check of five thousand dollars, and the other 18 accounts also paid substantial commissions. An order usually consisted of a railroad boxcar full of equipment; a half carload was considered to be a small order.

Don secured the two-letter call W6AM in 1926. In those days, the Department of Commerce assigned two-letter calls to amateur operators who also were commercial radio operators. The possession of a two-letter call was, of course, a mark of elitism indicating membership in the "first

Some years ago, Don's mobile rig was installed in the convertible pictured here.

family" of amateur radio. At that time if you wanted a license for a portable station, a separate license was required, and Don was given the call W6MA to cover that operation.

From 1926 until 1960, Don traveled extensively throughout twelve western states to call upon his customers. During all of those years, one of the pieces of luggage he carried with him was a "suitcase portable" containing an amateur transmitter and receiver. Arriving at some hotel, he would insist on having a top-floor room. If one was not available, he would move on to another hotel which did have one. After being shown to his room, he would open a window wide so that the drapes would hang outside the building, thus providing an easy means of locating his room from the roof of the hotel where he would suspend his antenna. After dropping the feedline from his antenna to the proper window and returning to his room, Don was soon in communication with his wife, Bertha, at home.

On these occasions, Mrs. Wallace would laboriously transmit code characters by looking at a code chart of International Morse which was under the glass on Don's desk at home. It wasn't long before she asked Don if she couldn't learn Morse, to eliminate that awkward code-chart method. Don's reply was, "Why not, indeed?" and a code-practice schedule of 30 minutes of intensive study daily was begun. Don added a proviso that if the prescribed practice was missed on any day, a *week* of additional practice would be the penalty.

One evening, with the Wallaces all dressed up and ready to leave home to attend a posh party, it was remembered that the practice for that day had not been done. Immediately they went to the ham shack and accomplished the code study necessary even though it meant being a half-hour late for the party.

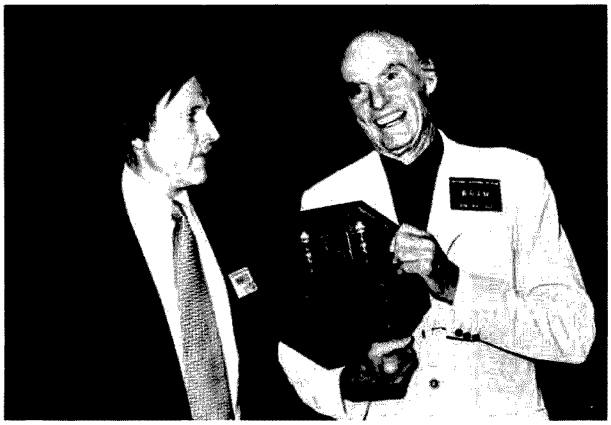
After two weeks of study, Bertha Wallace passed her amateur radio operator's examination and was assigned W6MA, and Don was told to use W6AM while operating portable in states other than California, followed by a slash bar and the number of the radio district in which he was operating.

Rhombic Farm

By 1938, a radio operator with whom Don had become acquainted during his Navy service, Tony Gerhardt, had become Chief Engineer of a new company called Press Wireless, formed by a group of twelve newspapers to transmit and receive their newspaper stories in order to avoid paying the high rates of the commercial telegraph companies. Gerhardt was charged with the responsibility of selecting a suitable receiving site to operate in conjunction with their transmitting location at Marina Del Rey, and he briefed Don on his problem.

From his earlier residence in the Long Beach area, Don had recognized the highest hill on the Palos Verdes peninsula as a superior location for an antenna farm, but had been unable to persuade the Vanderlip family, which owned 20,000 acres of prime land there, to sell any of it. Told of this, Tony said he had already tried but the Vanderlips still wouldn't sell. Don then reminded Tony that the *Los Angeles Times*, one of the owners of Press Wireless, was very friendly with the Vanderlips, running a full social page on the family every month. Don suggested that Tony contact Norman Chandler, publisher of the *Times*, and ask him to make the proposal to the Vanderlips.

Tony did this, with the result that Kevin Vanderlip agreed to sell Press Wireless a large parcel of land on the very top of the peninsula. Tony, a loyal friend of Don's, purchased all possible equipment needed for the new receiving station from the companies Don represented—including the wire and insulators for the eight 600-foot-long rhombic



Don is pictured being presented the DX Hall of Fame Award by Lloyd Colvin W6KG at the 1978 National ARRL Convention.

Shown here are the hams, editors, and writers (together with their local guides) from the United States who were guests of the People's Republic of China for a seventeen-day visit to that country in 1980. Don, third from the left, is easily recognizable as the tallest person in the group. The scene is the great bridge which crosses the Yangtze River.

antennas. Later, Don rearranged the antennas and erected nine new 1,000-foot-long rhombics, 140 feet high, which could be fed from either end to fire in eighteen different directions.

At the end of WWII in Europe, the FCC announced that shore stations such as Press Wireless no longer would be permitted to have radio links to their other stations since telephone lines were available. Press Wireless decided to move all its operation to the San Francisco Bay area (where it was headquartered) to eliminate the $32,000 annual telephone bill from the Palos Verdes station. Therefore, they purchased a site near Napa, California, and placed the 120-acre Palos Verdes site on the market in 1944.

Don's offer for the property was accepted. Press Wireless moved its 75 receivers to Napa, and Don moved his amateur equipment to the site, with its 35 major and 75 minor poles.

Since Press Wireless used poles which were only 75 feet high and some stood in valleys between hills, they provided an effective height of less than 75 feet. Don, in accordance with his lifetime policy of using long and high antennas, made 140-foot poles by placing two 75-foot poles butt to butt, securing them together with four 20-foot pieces of heavy four-inch angle iron, with eight heavy bolts through each pole.

Don, who is as spry and alert as a man half his age, has a pair of custom-made shoes constructed especially for the purpose of climbing poles, and he has done the maintenance of his antenna system for many years, although he has had some help recently on the 140-foot poles.

QRO Mobile

Don's super-powered mobile rig (1 kW on low bands; 250 W on 2 meters) had a valuable fringe benefit in addition to providing communications around the world from Don's automobile. Before her death, Don often drove his wife, Bertha, to one of the posh department stores in Long Beach and left her there to shop while he ran his own errands in other parts of the city. After an hour or two, he would return to the vicinity of the store and speak into the mike of his mobile rig as follows: *"Mrs. Don Wallace, will you please come to the front door of the store?"*

The store's PA system, overwhelmed by the powerful signal of W6AM, would always faithfully reproduce Don's announcement loud and clear everywhere within the store, thus saving him the trouble of parking and searching the store for Mrs. Wallace.

While Don's "broadcast" to his wife was intentional, his startling of patrons of Long Beach's State Theatre and of a nearby huge used-car sales was not. Movies were interrupted by, and the car-lot speakers picked up, an occasional "W6AM calling CQ."

Don won the first DX contest sponsored by the ARRL in 1926, and his record as champion DXer of the world is extremely well known. Wallace has talked to radio amateurs in more countries since 1955 than any other ham radio operator: 365 places classified as nations by the ARRL.

"It's like being a world-champion golfer for 25 years or being the world's champion runner for that long," Don says proudly (and deservedly so). He modestly credits his antennas for his DX success.

When the ARRL announced that a $25 plaque was available to amateurs for *each time* they headed the DXCC list, Don sent in his order for whatever number of plaques he was entitled to and asked that he be billed for their cost. However, *QST* determined that Don had headed the DXers list more than sixty times and that the cost of his plaques would be $1775. It asked for confirmation of such a large order before proceeding with it, and Don compromised and ordered only two representative plaques, one for CW and one for phone.

There wouldn't have been room for all of the plaques, anyway, since three of the four walls of Don's thirty- by forty-foot ham shack already are plastered with plaques, cups, and awards for his accomplishments during 72 years of hamming.

When Don twists the knob of the rotary switch which activates the 108 relays to select the rhombic antenna needed to fire a maximum signal to some area of the world, the clicking relays sound a bit like a World War I machine gun nest. Once the proper antenna has been selected, however, all is quiet, and Don is able to work DX stations that other amateurs cannot even hear.

When he is questioned as to how he is able to maintain his position at the top of the DXCC list, he modest-

ly states that it is not because of his own efforts but those of scores of his friends and fellow DXers who cooperate by advising each other when a new country becomes available. Don says the game is not what many people think. One always helps one's competitors. When Don was vacationing in Palm Springs, one of his DX competitors telephoned him about a new station on Revillagigedo Island. Don drove several hours to get back to his home station, and, thanks to his friend's tip, made the contact for a new country.

Trying his fist in American Morse code at the 1980 meeting of the Southern California Chapter of the Morse Telegraph Club may have brought back memories to Don of operating a five-block-long telegraph line which he and a friend constructed in 1910.

Items

● In October, 1980, Don, along with ten other hams, editors, and writers, was the guest of the People's Republic of China for 17 days of sightseeing and seminars. That made 91 countries visited, and he operated amateur radio in most of them.

● During his lifetime, Don has devised over 100 improvements in amateur radio equipment which have been accepted and manufactured by various companies.

● At least once a year and sometimes as many as four times a year, Don conducts an open house at his Radio Ranch. Radio amateurs with less deluxe stations of their own come to the Palos Verdes peninsula and view with amazement a really superb ham installation. Don is very gracious about accepting requests from ham radio clubs to be their guest speaker and always provides great entertainment.

● When interviewed in the early twenties, Don said, "Amateur radio for me till ninety." He has only five years to go to achieve that goal.

● When interviewed by the *Los Angeles Times* in 1979, Don stated, "Clicking the key and talking to radio hams everywhere in the world is just as exciting to me today as it was when I was a kid."

With that kind of enthusiasm after 72 years of hamming and with a lifetime of extraordinary achievements in wireless and radio behind him, there is only one word adequate to describe Donald Clare Wallace: Superham! ■

The Spider™ *Maritimer*™ Antenna ™
U.S. PAT. 4349825

The only multi-band amateur radio antenna designed specifically for use on ocean-going boats and in areas close to the ocean.

● Non-magnetic stainless steel mast with nickel-chrome plated fittings give the best protection against salt water corrosion.

● No switches of any kind—no moving contacts to corrode, ever!

● Four amateur bands without changing coils—10, 15, 20 and 40 meters. **PLUS**, add the Spider™Adapter collar and special resonators for commercial marine frequencies and you have **SEVEN** bands at your command at all times without any switching or changing coils.

● Less than six feet high so it can be stern-mounted on the transom for an easy installation.

● Approximately 50 ohm base impedance—requires no antenna tuner in the transmission line.

● SWR is approximately 1:1 at all selected resonant frequencies.

● Each resonator is tuned to the desired portion of the band by a tuning sleeve which slides over the outside of the resonator.

● ***Accessories for Marine Use***—Stainless steel and corrosion-resistant ball mounts, angle mounting brackets, stud mounts and quick disconnects. RG58C/U coaxial cable with non-contaminating jacket. Coaxial fittings. Copper foil ground strapping.

● *A note or phone call will get you full information and prices—include phone number.*

Courage for Would-Be Hams

Here's the inside story of how a worldwide network of hams is helping handicapped people get their licenses.

Would it surprise you to learn that your next QSO could be with a blind person, someone in a wheelchair, or a man who is allergic to almost everything?

More and more people with physical disabilities are discovering the fun and excitement of making new friends around the world through amateur radio. Among the organizations working to teach disabled people how to become hams is the Courage HANDI-HAM System.

The Courage HANDI-HAM System is an international network of able-bodied and physically-disabled hams dedicated to helping people with handicaps explore their interest in amateur radio and assisting them in obtaining or upgrading their licenses. Headquarters for the system is Courage Center, a United Way-affiliated rehabilitation organization located in the Minneapolis suburb of Golden Valley.

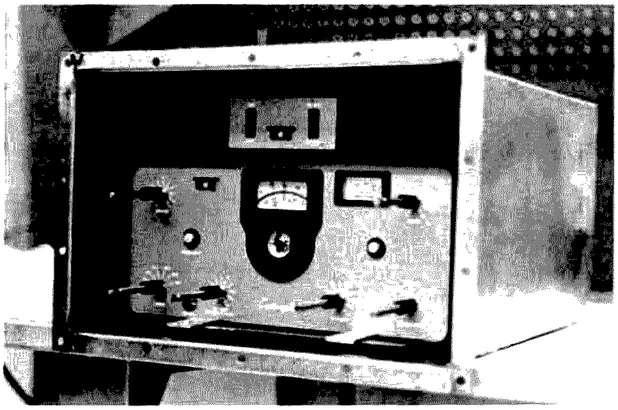
People with physical disabilities interested in amateur radio generally join the system after hearing about it from friends who are hams or reading about it in amateur radio publications. After contacting system headquarters, prospective students are matched with experienced members living in their areas for one-to-one instruction and counseling. Students are also loaned study materials and equipment. In return, they're expected to have a genuine desire to become amateur radio operators and must earn their own licenses.

Once students obtain

Blind HANDI-HAM member, Maureen Pranghofer KFØI, Minneapolis, is a student coordinator for the system. Though she feels amateur radio is an exciting hobby, her guide dog Allen isn't always that thrilled.

Blind HANDI-HAM Dick Eichhorn KBØAE, Minneapolis, is activities coordinator and station manager at the system's headquarters at Courage Center in Golden Valley, Minnesota.

During a typically busy morning at system headquarters, (L to R) John Balkus KØBFU, Minneapolis, and Malcolm Mackay III NØBQC, Minneapolis, check in with the nets while Rex Kiser WØGLU, Edina, Minnesota, "talks" to a hearing-impaired ham on a TTY hooked up to a standard transceiver.



The Courage HANDI-HAM System sealed this Century 21 transceiver into a stainless-steel box so it could easily be used by Bill Savada N5FLY, Falcon Heights, Texas, who is dangerously allergic to the plastic found in most equipment.

their Novice licenses, they can enjoy many other benefits of being HANDI-HAM members: participating in regularly scheduled nets to meet other members, enjoying the fellowship of other hams while improving their skills in contests and "Radio Camps," receiving instruction to upgrade their licenses, and enjoying the satisfaction of introducing other people with physical disabilities to amateur radio.

The Courage HANDI-HAM System was founded by Ned Carmen WØZSW and other interested hams in Rochester, Minnesota, in 1967. Carmen, who had long been fascinated with the idea of organizing a network of handicapped radio operators, finally decided to act on his idea following a thunderstorm watch in Rochester on April 30 of that year.

During the watch, Carmen asked two Catholic sisters in Rochester, Sister Lauren Weinandt WNØRRJ and Sister Judith Simon WNØQVN, to activate their respective stations, "Sky Wave" at St. Mary's Hospital and "The Voice of Assisi" at the Assisi Heights convent, and join in a weather watch.

The watch worked so well that Carmen invited the sisters to help organize the "Minnesota HANDI-HAM System." A 14-member steering committee was formed which met on the air every week to suggest policies and discuss problems. The steering committee soon became the system's board of directors, with a six-member management committee serving as its chief officers.

By the fall of 1967, the system had helped four new Novices receive their licenses. In September of that year, Carmen was honored by the Rochester Chamber of Commerce for teaching amateur radio to homebound people and obtaining equipment and transportation for them. His work also earned him the "Good Neighbor" award, given by WCCO, a clear-channel commercial radio station in Minneapolis. By that time, the system had ten students enrolled.

As time went on, the Minnesota HANDI-HAM System gradually began to make a name for itself. In 1968, the Piconet (Public Information Convenience or Necessity Network) and the Rochester Amateur Radio Club invited the system to co-host their Winter Hamfest. By the summer of 1969, the system made itself known to the nation's amateur radio operators when 26 of its severely disabled members took part in the National ARRL Convention in Des Moines, Iowa.

Sister Alverna McLaughlin WAØSGJ, Minneapolis, Educational Services Coordinator for the system, was a member of the group that attended the convention, and she wrote about the experience in a recent issue of the system's "HANDI-HAM World" newsletter:

"The great HANDI-HAM caravan left for the National ARRL Convention in Des Moines at 7:10 am on Friday, June 20, 1969 . . . ten-meter handi-talkies were in each vehicle so we could communicate with each other when necessary . . .

" . . . The HANDI-HAM display at the convention was adorned with promotional posters explaining the steps, in pictures, of how a HANDI-HAM member gets his amateur ticket . . . From the comments of the guests who stopped by, we had the nicest booth there . . .

" . . . The HANDI-HAM System was the talk of the convention. Hams who were blind pushed wheelchairs and the hams in wheelchairs told the blind people which way to go . . ."

Once the system became known to the amateur radio community, it grew steadily as more able-bodied hams volunteered to be instructors and more people with disabilities eagerly signed on to learn the hobby. Before his untimely death from a heart attack in 1972, Carmen, with the support of several individuals, companies, and organizations throughout Minnesota, expanded his Minnesota HANDI-HAM System into a network of 70 students and 240 disabled and able-bodied members.

To further expand its services and streamline fundraising, the system affiliated itself with Courage Center in 1974. The organization now boasts 3160 members in all 50 states and 27 countries.

But the real story of the Courage HANDI-HAM System is its disabled members who have unlocked the door to a broad new world through amateur radio:

● Hams chewing the rag with Maureen Pranghofer KFØI, Minneapolis, never suspect she's blind, and that's just the way she likes it.

"When people talk to me on my rig, they can't see that I'm blind," says 26-year-old Pranghofer. "Because of this, they're generally more re-

Long-time HANDI-HAM member Jim Mowery KØZWG (left), Fargo, North Dakota, who has cerebral palsy, checks out a rig at headquarters while Dick Eichhorn KBØAE helps out.

laxed and relate to me rather than to my disability."

Pranghofer was introduced to the system when she was a sophomore in high school and was so captivated by ham radio that she earned her Novice license after only two months of intense study.

"I learned my code from braille and memorized it almost overnight," she said. "The electronics theory was tougher because I had to memorize it from tape recordings."

Nowadays, Pranghofer, the proud owner of an Extra-class license, works full-time as a student coordinator for the system, while sharing housework with her husband Paul, a computer analyst who is himself disabled, born without arms and legs.

"I don't get on the air as often as I used to, but I try as often as I can," she says. "Amateur radio is a satisfying hobby for disabled people because it's something they can do that many able-bodied people can't."

She adds that her involvement in the system has rewarded her in many ways.

"The Courage HANDI-HAM System got me started in amateur radio by providing me with the equipment, instruction, and encouragement I needed," she said. "Now that I'm the student coordinator, I enjoy the challenge of turning other disabled people on to ham radio."

●Marlin Gilman WAØAUX has used a wheelchair for over 30 years because of severe arthritis, but that hasn't prevented the 45-year-old Earlham, Iowa, man from making DX contacts in 50 countries.

"Amateur radio has helped me socialize with others and generally become more involved in life," he says.

A next-door neighbor introduced Gilman to amateur radio in 1960, and he has since progressed to his Advanced license, operating a station on his family's farm.

"I'm active on almost every band, and I check in with various nets all day," he says. "I enjoy staying in touch with old friends and making new ones."

But ham radio isn't all fun and games for Gilman, who takes his obligation to public service seriously.

"Back in 1967, Missouri was hit by a heavy snowstorm and cars and trucks were getting stuck left and right," he said. "I helped relay emergency calls to the police from motorists and truckers."

Gilman credits the system with allowing him to join a growing family of disabled and able-bodied hams.

"The people on the air are warm and friendly and I get a big kick out of chewing the rag with hams all over the world," he says. "The Courage HANDI-HAM System has opened a world to me that accepts me for what I can do and ignores what I can't do."

●Amateur radio is even more important to General-class Bill Savada N5FLY, Falcon Heights, Texas, because it helps him ease the isolation of living by himself in a porcelainized stainless-steel trailer located in a sparsely inhabited corner of the state, 60 miles south of Laredo. He can't live in a city, because it would probably kill him.

Savada has universal allergy, which brings on violent, often dangerous, seizures when he's exposed to everyday materials most people take for granted, such as synthetic clothing, cosmetics, plastics, pollen, air and water contaminants, and a host of others.

In 1979, the ARRL put Savada in touch with the system because he faced a tremendous obstacle: He couldn't operate standard radio equipment because he's allergic to the plastic found in most rigs.

System director Bruce Humphrys KØHR, Minneapolis, with the help of several Twin Cities area engineers, companies, and organizations, designed a non-allergenic stainless-steel box with stainless-steel control extentions into which he sealed a standard transceiver. The box was shipped to Savada in March, 1980. Over the phone they agreed that Savada would test his rig by attempting to contact Humphrys at 11:00 am that April 1.

"I was really worried," Humphrys said. "I was worried about whether we'd sealed the box tight enough so Bill wouldn't react to it, worried about whether or not the box had been damaged in transit, and worried about whether or not the rig would overheat and blow up!"

But suddenly, a slow, strong, steady stream of code came over the air. It was Savada, signaling the end of his total isolation.

●The Courage HANDI-HAM system is always looking for new members, either disabled or able-bodied. Able-bodied hams are needed to serve as one-on-one instructors and to help set up rigs and antennas for disabled members.

In addition, people wishing to clean out their basements of old or surplus equipment and parts will find a ready taker in the system, which relies heavily on donated equipment. For information, contact Bruce Humphrys, Director, Courage HANDI-HAM System, 3915 Golden Valley Road, Golden Valley, Minnesota 55422, (612)-588-0811. ■

Fig. 2. Program listing, alphabetical sort by prefix.

The active DXer needs a way to monitor a count on his countries both worked and confirmed. The program included here is ideal for a computerized station. The data can be inserted in any order and the sort portion of the program will alphabetize the prefix or the country.

The program is written for a TRS-80, but it can be modified for other computers. The sort portion of the program takes a little time (about 5-6 minutes for 100 countries), but that affords the operator time to make out QSLs or other QSOs while running.

The program as listed is the alphabetical sort by prefix; by changing lines 190 through 250, the program will alphabetize by country.

One thing must be noted: The computer places numbers prior to letters (i.e., 3B8, 7X2, 8P6); in other words, all country prefixes starting with a number will be listed prior to the alphabetical prefix routine.

This and my 2nd op make DX work a pleasure; it also saves time. ■

Warning: Your Time's Up!

Don't get taken by surprise. This timer add-on will tell you when to ID before it's too late.

Ken Henry's ten-minute-timer design[1] caught my eye as an interesting and worthwhile project. I immediately proceeded to assemble this digital gem and it has been counting out the minutes without a flaw ever since. Although to some a timer may be considered a minor convenience, I find it very helpful in cutting down on the reporting of callsigns. Once in ten minutes is enough!

However, I soon discovered that it is very easy to become overly dependent on the ten-minute alarm. Often I forgot to watch the readout and "timed out" when I could not immediately report my call. Finally, I decided that a warning to draw my attention to an approaching ten-count was a necessity. Fortunately, this proved very easy to do.

Fig. 1, the connection diagram for the 7447/7448 decoder, reveals that a blanking input is available at pin 4. When a low is applied to this pin, all segments of the readout are turned off. Therefore, applying an alternating high-low input to pin 4 will flash the time count and provide a visual warning of an approaching ten-count.

The main problem was to find a logic source to initiate the blanking input at the desired time count. Note, in Fig. 2, that decoder-input D logic is low till the end of the seven-count and then goes high for the last two counts. This high, used in combination with input A logic, can provide a flashing display at the eight- or nine-count as desired.

All that remains is to convert the input D logic source to an alternating high-low at decoder pin 4. This is done easily with a single 7400 NAND gate. As shown in Fig. 3, to obtain a flashing nine-count, pins 1 and 2 of U1A are connected to pin 7 (input A) and pin 6 (input D) of the decoder. At the eight-count, pin 6 goes high. Since pin 7 is low at this time, nothing happens. However, at the nine-count, pin 7 also goes high. With both pins 1 and 2 of U1A high, pin 3 goes low, forcing U1B pin 11 high which in turn is connected to U1C pin 4.

At this point, we need only to provide an alternating high-low logic input to pin 5 and the job is done. Fortunately, the once-per-second pulse at the output of IC2 pin 11 in the timer counter chain provides the perfect source. With U1C pin 4 high, and a high-low input to pin 5, pin 6 will go low and turn off the display once per second.

If you prefer a two-minute warning, connect U1A pin 1 to Vcc with a 2.2k resistor. This holds pin 1 high

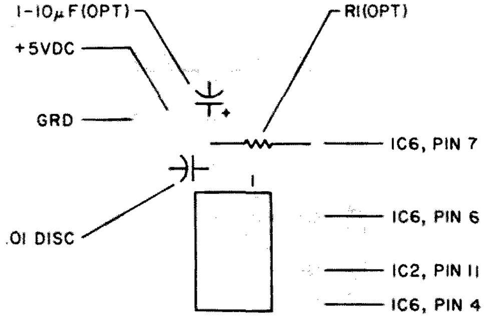

Fig. 4. Foil side of the circuit board and the connection diagram.

so that when pin 2 goes high at an eight-count, flashing action will begin. Pins 9 and 10 are connected to ground, or one pin to Vcc, to force output logic high. Avoid floating inputs on unused gates.

See Fig. 4 for a PC board layout. This circuit is so simple that perfboard is probably more appropriate. Be sure to connect C1 as close to pin 14 as possible. C2 can be any value between 1 and 10 uF and is required only if the power supply is not on the circuit board. Connect C2 at the point on the board where the Vcc lead is attached.

The K3VTQ timer is a terrific project for the aspiring builder. For those of you who do not have a copy of the May, 1977, issue of *73*, an SASE will bring a copy of the original article along with a later article[2] which provides a circuit-board design. ■

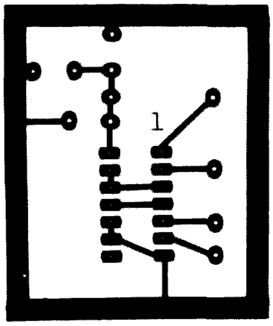

Fig. 5. Circuit board.

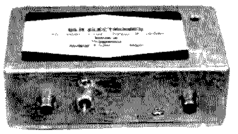
HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in **AMATEUR** and **COMMERCIAL** systems.

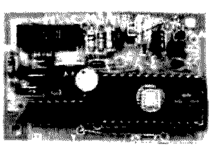


- 40 to 1000 Mhz - tuned to your frequency
- 5 large helical resonators
- Low noise - High overload resistance
- 8 dB gain - ultimate rejection > 80 dB
- 10 to 15 volts DC operation
- Size - 1.6 x 2.6 x 4.75" exc. connectors
- **FANTASTIC REJECTION!**

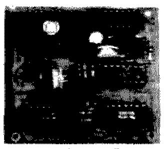
Typical rejection:
±600 Khz@144 Mhz: −28dB
±1.6 Mhz@220 Mhz: −40dB
±5 Mhz@450 Mhz: −50dB

Price - **$79.95** bipolar w/RCA jacks
Connector options: BNC $5, UHF $6, N $10
SUPER HOT! GaAs Fet option $20

AUTOMATIC IDENTIFIERS



ID-1



ID-2

- For transceivers and repeaters - **AMATEUR** and **COMMERCIAL**
- Automatic operation - adjustable speed and amplitude
- Small size - easy installation - 7 to 15 volts DC
- 8 selectable, reprogrammable messages - each up to 2 min. long
- Wired, tested, and programmed with your message(s)

Model ID-1 - $39.95 Model ID-2 w/2 to 10 minute timer - $59.95

We offer a complete line of transmitter and receiver strips and synthesizers for amateur and commercial use.
Request our free catalog. *Allow $2 for UPS shipping - Mastercard and VISA welcome*

Babysit Your Battery

This intelligent charging circuit will pamper your emergency power system. It's what every repeater needs.

Robin Rumbolt WA4TEM
1134 Glade Hill Drive
Knoxville TN 37919

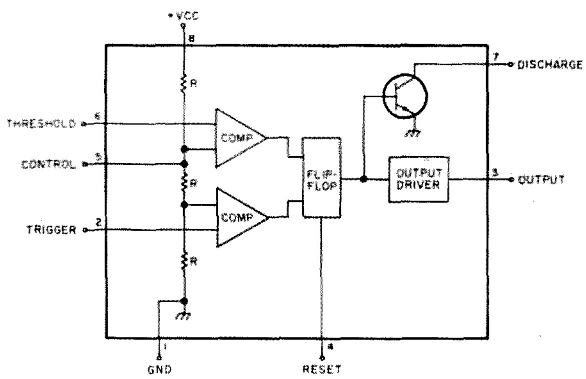

Fig. 1. NE555 timer block diagram.

Many solid-state repeaters nowadays use large lead acid batteries for standby emergency-power sources. One problem that our repeater club had with such a system was that of keeping the battery charged without overcharging it. Keeping a charger on it continuously would have tended to boil the acid out of it after only a short time, rendering the battery useless. Repeated trips up the mountain to replace or refill batteries were out of the question, so a simple regulator was designed to charge the battery when needed and discontinue charging when the battery reached full charge.

The Circuit

The key element in this simple circuit is the good ol', ever popular NE555 timer integrated circuit. No, the circuit does not time the charging, but it does make use of the 555's internal voltage comparators.

The block diagram of the 555 is shown in Fig. 1. The 555 has a resistive divider composed of three equal resistances connected between power and ground.

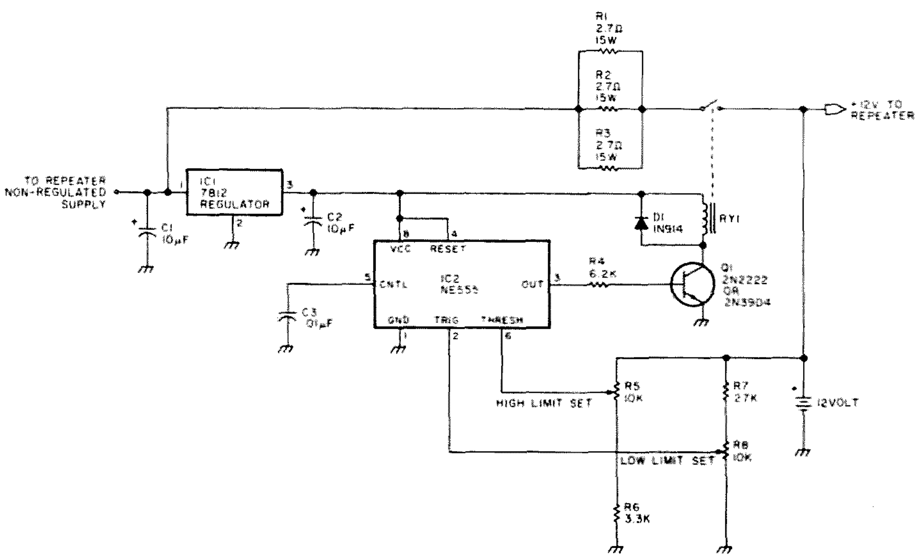

Fig. 2. Regulator schematic.

Two comparators are connected to this divider network in such a way as to provide comparisons between 1/3 and 2/3 of the supply voltage. A flip-flop controlled by the comparator's outputs turns on and off the output stage. The output stage is turned on whenever the voltage on the trigger input (pin 2) goes below 1/3 of the supply voltage. Similarly, the output is turned off whenever the voltage on the threshold input (pin 6) goes above 2/3 of the supply voltage. Therefore, to use the 555 as a charger regulator all we have to do is stabilize the supply voltage at 12 volts and scale down the trigger and threshold voltages. The schematic of the simple charger is shown in Fig. 2.

Resistors R7 and R8 form a voltage divider set in such a way that when the battery voltage falls to a lower limit (11 volts in our system), the voltage at pin 2 of the 555 is at 1/3 supply or, in our case, four volts. At this point, the output of the 555 (pin 3) goes high turning on transistor Q1 which in turn activates the charger relay, RY1. This relay connects a charging voltage to the battery through current-limiting resistors R1, R2, and R3. Charging then continues until the battery reaches a high limit (14 volts in our system). Resistors R5 and R6 scale this voltage so that the threshold voltage at pin 6 of the 555 is then at 2/3 of the supply voltage (in our case, eight volts). The output of the 555 then turns off, stopping any further charging. Simple, isn't it?

The unregulated output of our repeater's main power supply is about 16 volts. Since we set our lower charger trip voltage at 11 volts, we had a maximum voltage difference of five volts across the current-limiting resistors. We determined that a charge of around 6 Amps would be adequate. Ohm's law then showed that a resistance of slightly less than 1 Ohm at a power rating of about 30 Watts was needed. Three 2.7-Ohm, 15-Watt resistors from my junk box, wired in parallel, came close enough.

Adjustment

The circuit can easily be preset prior to installation at the repeater site. Connect a variable power supply set to 12 volts in place of the battery and a fixed supply of 14–18 volts to the 7812 regulator. Resistors R5 and R8 should be set to the center of their ranges. Now adjust the variable supply to your desired lower-limit voltage. Adjust R8 to the point where the relay is just activated. Then adjust the power supply to your desired high-limit voltage. Adjust R5 to the point where the relay just falls out. Check it by turning your power supply down to a voltage below your lower trip point. The relay should then pull in and stay energized until you adjust the power supply to a voltage higher than your upper trip point.

Conclusion

This charging circuit has worked flawlessly in our repeater for over a year now. It has shown no signs of rf sensitivity or any kind of malfunction. Although the repeater is remotely switched to battery operation every weekend, water has been added only once. No evidence of significant boilover has been observed. It is a simple circuit that works fine every time. It is just exactly the type of circuit that is needed for a very remotely located repeater.

One caution: Before connecting this circuit to your repeater's main power supply, be sure that the supply can handle both your repeater's maximum current needs and the maximum charging current going to the battery! Otherwise, popped fuses or components can result when the charger is connected. ■

PO Box 323
North Stratford NH 03590

AS FAR SOUTH AS POSSIBLE

The by-product of an effort to break from the eight-to-five norm was my trip to the south polar ice cap. The assignment was the construction of a 26-mile-long dipole antenna at the National Science Foundation's Siple Station.

Siple Station, located at 76° south latitude and 84° west longitude, conducts upper atmospheric and magnetospheric research. The lengthy dipole is used in conjunction with a 200-kW ULF transmitter and receiver in the study of Whistler-wave phenomena.

Whistler waves occur naturally as a phenomenon associated with distant lightning. The signals follow the Earth's magnetic lines of force, reaching altitudes of several Earth radii while traveling to the opposite hemisphere and often returning on the same path.

The antenna project offered an opportunity to venture over the horizon from Siple Station and travel where no humans had ever been. Because we had the antenna to follow, we were able to work when weather conditions were less than ideal. This provided a chance to witness unique weather.

When the sun was obscured by clouds, the horizon would vanish and the snow's surface would lose all definition. All perspective would be lost. A traveling snow tractor or a fellow worker would appear to float in midair. This condition is known as a whiteout. With a moderate to heavy fall of snow and the associated low visibility, a whiteout would take on a dimension that kept us secured at the station.

During free time, I had the chance to use Siple's amateur-radio station, KC4AAD. A regular schedule for phone patches was attempted using KWM-2A gear. A sloping-V antenna with 562 feet on each leg was used to radiate the signal. The transmitter was located 50 feet beneath the snow in the station proper. The station, built on the surface in 1978, has since been covered by the ever-accumulating snow. It was at Siple that I experienced working my first pileup from the "other end." Now that I've had time to think, I feel that I could have handled it better.

When the antenna project was completed, I was sent further south to work as meteorologist at Amundsen-Scott Station at the South Pole.

The weather at the Pole was extremely cold and quite dull. I never saw the temperature rise above −18° F or fall below −40° F (remember that this was summer). The continuous wind did not rise above 25 miles per hour. There was no snowfall. The air was too cold. Instead, a snow phenomenon known as diamond dust frequently fell from the deep blue sky, faithfully adding to the already phenomenal 9000 feet on the ground. The air had no fragrance, no depth. It was sterile. No birds flew, no wild animals sauntered by; not even bacteria lived outside the station at the South Pole.

I also found time to work the amateur station at the South Pole, KC4AAA. The station's Collins KWM-2A was fed into a six-element tribander up about 75 feet. The antenna's rotor was enclosed in a heated box.

After the phone-patch list was cleaned up (and barring any pileups), I would take time to do what I like to do: rag-chew. The 20-meter band would be searched for some lonely CQ in the night, and I would answer. I think that I received more of a thrill than the other station when I listened to the response of having contacted the South Pole! I also enjoyed armchair contacts with my old friends back home in northern New Hampshire. Once they even patched me into the Granite State FM Net on two meters via the Mount Washington K1OIQ repeater.

I was disappointed that Brian Combs KA3JXR and I did not get to use the controlled-current distribution (CCD) antennas sent to Brian by W4FD and W4ATE as mentioned in the July, 1983, issue of *73*. The powers that be had other plans.

I am looking forward to more fun in the deep south as I have accepted a contract position as radio operator/meteorologist at Siple this season. I may even get a chance to winter-over this year!

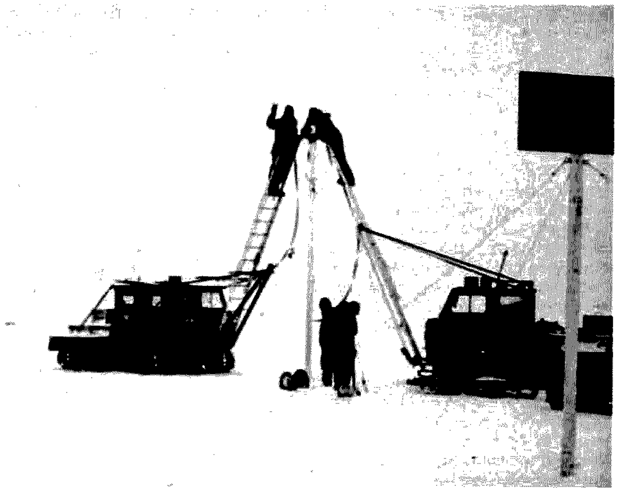
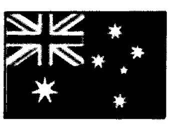
Amateur-radio station KC4AAD at Siple Station, Antarctica. Brian Combs KA3JXR is seated at the mike operating DX from "the other end."



The last connection is made on the 26-mile-long ULF dipole antenna at Siple Station. Four thousand feet of salt-free ice (accumulated snow) beneath the antenna provides insulation from earth ground.



AUSTRALIA

J. E. Joyce VK3YJ
44 Wren Street
Altona 3018
Australia

Many countries, to their credit, have had such famous sons as Marconi, Bell, and Morse, whose endeavors in the field of communications are world renowned. Other countries have had their own pioneers in the field of radio communications but they have not received, or perhaps wanted, the world recognition they deserve.

One such person was Alf Traeger, the designer of the Traeger Pedal Radio.

In the year 1907, at the age of 12, he designed his own telephone using the prongs of a pitchfork, two tobacco tins, and some charcoal granules, linking up the farmhouse and an outlying shed. In 1926, at the age of 31, he obtained his amateur license. When John Flynn (the father of the Flying Doctor Service of Australia) was looking for a transceiver that would be cheap and simple to operate on Australia's outback stations and ranches, he contacted Alf Traeger.

After much experimenting, Alf came up with a transceiver that operated on the bicycle-pedal system. It drove a dynamo, thereby leaving the hands free to operate a CW transceiver. This had its drawbacks, as not all people knew Morse code, so, after experimenting, Alf added to his transceiver a keyboard that could transmit Morse letters at a governed speed. And all this back in 1926!

His transceiver was crystal-controlled, and a steady frequency was maintained whether you pedaled hard or slowly. I, for one, spent many tiring hours pedaling away for the station owner's wife or children, while she gossipped or the children got the only education possible for them from a teacher who was 1000 miles or more away.

By 1937, the Morse keyboard was replaced by a radiotelephone system which, while pedaling, left both hands free to either adjust the knobs or swat flies.

Pity the person who was either injured or sick before the advent of Traeger's transceivers. It usually meant a horseback ride of a week or more before help could arrive at some of the remote areas, with the patient either curing himself, suffering pain for a week, or dying. Unfortunately, many people did die. With the advent of Traeger's transceiver and the Flying Doctor, what was once a week's delay in medical help became only hours.

It was not all serious, though; it did have its lighter moments. For example, we had on our station a chap named Andy who had not been home to see his wife for six months. She lived in the nearest town, some 200 miles away. He finally decided to visit her for a get-together. While en route, we sent an on-the-air telegram to her (remember, everybody used to listen to these messages, all over the whole of

outback Australia). The text was "Coming home, feeling randy, hope you're the same. Love, Andy." He wondered why his reception at home alter six months away was lees than cool, until he was told of the prank.

With mates like us, who needed enemies?

Perhaps there is still a place today for the concept of pedal radio. Where there is no domestic power, flat batteries would be a thing of the past. How many DXpeditions have failed through generator failure in remote areas? If they took along a set of pedals with an efficient beam, they could still operate as all the Australian outback did, way back in 1926, thanks to Alf Traeger's Pedal Radio.

Brazil

CW AWARDS

Since March, 1975, when the Brazilian CW Picapau Carioca Group (Carioca Woodpeckers Group) commemorated its tenth anniversary, a sweeping awards program has been offered to the world's radio amateurs. This was the first group created in Brazil, and it is now 18 years old.

Well-balanced rules for DX participants and an interesting program for Brazilian hams brought such great participation that a TRS-80 Color Computer has been brought into use to handle the whole business, including the PPC Hunters Club, an exciting competition developing extraordinary interest among Brazilian radio amateurs.

Special care is taken for DX operators, so it will be easy to find PPC members operating all DX bands. Quick delivery of QSLs and awards are considered important "musts" by the group.

Members are PP1IR(B&P), PY1AFA, PY1AN, PY1ARS, PY1AVV, PY1AYE, PY1BLG, PY1BOA, PY1BUL(YL), PY1BVY, PY1CBW, PY1CC, PY1CCE, PY1DFS, PY7CGV(YL), PY1CIP, PY1CKV, PY1CTP, PY4CZ, PY1DFF, PY2DHP(YL), PY1DMZ, PY1DUB, PY1DUJ(YL), PY1EIR, PT9EJ, PY1ETP, PY1ETY, PY2EW, PY1EWN, PY2FWR, PY2FWT(B&P), PY6HL, PY1HQ, PY4PZ, PY1RJ, PY1SJ(YL), PY1SW, PY1VB, PY1WA, PY1WDS, PY1TG, PY1AAU, PY1DMX, PY1EBK, and PY1DGB. We are very happy to invite you all to join the fun of the PPC CW awards program!

PPCAW—Work five stations of PPC members.

PPC*DX*—Work 50 stations, suffixes forming international prefixes, according to the ARRL list, e.g., WA2PY, SM1*LU*, UK2VE, using only two-letter suffixes. To form one-letter prefixes, use one, two, or three *same*-letter suffixes, e.g., KA4*F*, G3*FF*, or PY5*FFF*. Maximum of ten stations from the same country (except if from Brazil, where there are no limits). Endorsements or credits for each new 10 stations, until 100 total stations.

PPCPY—Work 27 different stations with two-letter suffixes which are the same as Brazil's 27 states' two letters: AC, AL, AM, AP, BA, CE, DF, ES, FN, GO, MA, MG, MS, MT, PA, PB, PE, PI, PR, RJ, RN, RO, RR, RS, SC, SE, and SP. Maximum of 6 stations with the same prefix, except for no limits with Brazilian station QSOs.

PPXA—Work 50 different prefixes from North, Central, or South America. Credits for each new 50 prefixes until you reach a total of 300 stations.

PPQRA—Work 17 different stations using suffix's first letters to form: P-P-C P-I-C-A-P-A-U C-A-R-I-O-C-A. Credits for same task but using second suffix letters and third suffix letters.

PPC3A—Work 25 countries in North, Central, and South America, ARRL list. Any band, but 3 Americas must be represented for the basic award. Credit for each new 10 countries in North, Central, or South America.

5BPPC—Work five different Brazilian prefixes on each of 5 bands, 10-15-20-40-80/160, and one PPC member per band. If it is in the same claimed band, the PPC OSL is valid for that task, too. The basic award is obtained for any complete band and PPC QSL. Same prefixes can be worked in other bands if different stations. Contacts valid only after 01-01-81 for 5BPPC.

QSOs since March 22, 1975, are valid for all awards except 5BPPC. No QSLs needed; just send logs signed by your radio association or two radio amateurs. Send GCR list indicating number, call, date, and declaration that all QSOs were two-way CW signed by association or two radio amateurs; include one of your QSL cards for PPC files.

GCR, log, and a 5-IRC fee for each award must be sent to PPC Award Manager, PO Box 18003, Rio de Janeiro, RJ 20781, Brazil.

For credits, send an SASE and 1 IRC.

CANADA

CARF News Service

Keeping a radio-station log is no longer necessary, except for Amateur-class operators who will need logs and QSL cards for proof of operation when applying for 10-meter and VHF phone privileges. DOC promulgated the change on June 22. Another change in the regulations made at the same time makes it easier for those with Amateur-grade certificates who live far from exam centers to obtain authorization for Advanced-class privileges, good for one year. Logs and OSL cards are also required when applying for this permission. Minor changes have also been made to the titles of the various Certificates of Proficiency.

DOC soon will ask for public comments on special considerations to be written into the regulations for handicapped candidates for exams. Also up for comment will be a change to require candidates for the Advanced-certificate code test to know figures and punctuation marks. At present, these are required only for the Amateur-class test. Comment will also be asked on a proposal to drop licensing of scanning receivers, a requirement which has proven practically unenforceable.

Good news for those plagued with power-line and appliance interference. DOC plans to proceed with regulations governing rf noise from these sources. Other regulations to cut the interference from electronic appliances, computers, and games are now being drafted by the Department. The regs will include what is termed "digital apparatus" and will be aimed at preventing dumping into Canada equipment which can't meet US standards.

COLOMBIA

Abelardo (Lalo) Santos V. HK3EOJ
PO Box 88937
Bogota
Colombia

NEW RADIO-AMATEUR RULES

The Colombian government, through the Ministry of Communications, has issued new radio-amateur rules which will be implemented in the coming months. They include some specific norms for the use of amateur satellites emphasizing the technical and experimental aspects of this service, in accordance with the international regulations.

Regarding radio-amateur licenses, they will be issued to hams from the age of fourteen: Novice; Third class, after holding a Novice license for one year; Second class, after one year of holding Third class; and, finally, First class to those hams having held a Second-class license for a minimum of two years and passed a stringent examination.

First- and Second-class licenses are permanent, while those below must be renewed every four and two years, respectively. Callsigns must be used at the beginning and at the end of each transmission.

One of the most interesting aspects of the new regulations relates to nationals holding foreign licenses. They can obtain a Colombian radio-amateur license without having to pass any tests. Besides, the Colombian license will be of equal category to the foreign one.

As for foreigners residing or visiting the country, their valid license will automatically be honored by the Colombian Ministry of Communications with the same category and privileges without having to submit to examination, and they will retain their own callsign followed by the HK prefix plus the number of the zone from which they are operating. A consular certification from the country of origin is required by the Ministry of Communications for the issuance of the permit.

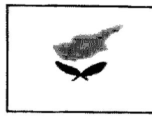
There are nine amateur zones in Colombia, namely, HK0 for the islands and maritime-mobile operation; HK1 for the Atlantico, Bolivar, Cordoba, and Sucre provinces (Departamentos); HK2 for the Guajira, Magdalena, Cesar, and Norte de Santander Departamentos; HK3 for Cundimamarca (this includes Bogota), Meta, and the Vichada Commissary (Comisaria); HK4 for the Antioquia and Choco Departamentos; HK5 for the Departamentos of Valle del Cauca and Cauca; HK6 for Caldas, Tolima, Huila, Quindio, and Risaralda; HK7 for Santander, Boyaca, and the Intendencia of Arauca and Casanare; HK8 for Narino, Caqueta, and the Intendencia of Putumayo, and HK9 for Comisarias of the Amazonas (the southernmost tip of Colombia bordering Brazil and Peru), Vaupes, Guainia, and Guaviare.

If a holder of a valid radio-amateur license is dead, any one of his relatives can keep the license provided he/she passes the tests and other requisites within one year of the original holder's death.

To operate a ham-radio station, there is also a new requisite besides holding a valid radio-amateur's license, in the form of a contract signed with the Ministry of Communications and the payment of a small tax. The contract is valid for periods of two years for Novice licensees, four years for Third class, and five years for those with First- and Second-class tickets, renewable for equal periods of time.

The use of phone-patch traffic continues to be prohibited except in emergency situations and for special cases involving communications from the so-called "National Territories" which are those sparsely-populated areas bordering Venezuela, Brazil, Panama, and Peru.

Finally, and most encouraging, is the proviso whereby the Ministry of Communications from now on will issue special honorific certifications (diplomas) and decorations to those radio amateurs (Colombian or otherwise) who have rendered special and distinguished (outstanding) services for the benefit of the community and humanity.



CYPRUS

Aris Kaponides 5B4JE
PO Box 1723
Limassol
Cyprus

THE CYPRUS AWARD

The Cyprus Award is being sponsored by the Cyprus Amateur Radio Society. It will be awarded to any licensed amateur-radio operator outside Cyprus who makes a specified number of two-way contacts with licensed amateurs on Cyprus.

To reduce as far as possible any advantage accruing to stations because of their geographical location and to encourage activity on the less frequently used bands, the certificate will be awarded on a points basis deteremined by the zone location of the station and the frequency bands used. This is shown in the table.

The total number of points required to win the award is dependent on the number of bands used:

If all contacts are made on only one band, 32 points are required.

If the contacts are made on any two bands, 24 points are required.

If the contacts are made on any three bands, 16 points are required.

If the contacts are made on any four bands, 12 points are required.

Any mode of emission may be used, but operation must be in accordance with standard amateur-service practice. Contacts must be made after April 1, 1973. A certificate awarded for contacts made in the VHF bands will be suitably inscribed. Contacts with any one Cyprus station can count only once per band.

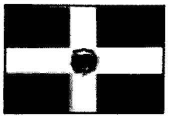
	Points per contact, by band (in MHz)							
	1.8	3.5	7	14	21	28	144	432
CQ Zone								
20	8	2	1	1	2	4	2	8
1, 2, 3, 6, 7, 10, 12, 19, 24, 25, 26, 27, 28, 29, 30, 31, 32	16	8	4	2	4	8	-	-
All Others	8	4	2	1	2	4	16	32

Cyprus Award points schedule.

To claim the award, copies of log entries with the following information should be submitted: date/time GMT, station worked, frequency band, and signal reports in and out. Each log sheet should be headed with the callsign, zone number, and full postal address, preferably typed or printed in block letters. These should be supported by the appropriate QSL cards or a certificate from the applicant's national society certifying that the QSL cards have been made available to them. In countries without a national society, a similar certificate signed by two other amateurs will suffice.

Log sheets accompanied by ten IRCs or US$2 or the equivalent should be sent to the Awards Manager, Cyprus Amateur Radio Society, PO Box 1267, Limassol, Cyprus.

The log entries will be checked and, at the discretion of the Cyprus Amateur Radio Society, the certificate will be awarded. Unsuccessful applicants will be notified of the reason for rejecting their claim.



DOMINICAN REPUBLIC

M. F. Pimentel (Tim) HI8MFP
PO Box 2191
Santo Domingo
Dominican Republic

Greetings from the Dominican Republic to all the readers of *73*. From now on we will cover interesting news concerning ham radio in this beautiful island in the Caribbean.

We will also be glad to help you in getting any HI QSL which you have failed to receive, work out a schedule for a particular band, or answer any of your questions pertaining to the ham scene here.

The Dominican Republic (HI) shares the Hispaniola Island with Haiti (HH) in the Caribbean Sea between Puerto Rico and Cuba. The Dominican Republic has a territory of 48,442 km^2 and Haiti has about 26,700 km^2. The capital city of the Dominican Republic is Santo Domingo; it holds one and a half million people of the total population of six million.

The country is divided into nine zones for ham-radio purposes. Zone 1 includes the islands of Beata and Alto Velo, which belong to the Dominican Republic, and some islets in the surrounding area. Zone 2 includes three islands, Saona, Catalina, and Catalinita. These first two zones are activated only in DXpeditions since they have no permanent ham-radio residents.

The first DXpedition to Beata Island (HI1RCD) was in 1979; it was run by a group from the Radio Club Dominicano. Zone HI2 was activated for the first time on Saona Island in 1977 by another group from the above-mentioned club. Later, in the years of 1980 and 1981, some DXpeditions were also made to Catalina Island, again by the boys of the Radio Club Dominicano.

The northern and central areas of the country correspond to Zone 3. At the present time, there are well-organized and very enthusiastic ham-radio operators among the Zone 3 members of the Radio Club Dominicano. They are very active on 2 meters and also on the other bands. There's great enthusiasm for DX and contests. Right now, we could state that this zone is the most active in ham radio in the Dominican Republic, having around 100 active ham operators.

Zone 4 holds only two active operators, while there's only one in Zone 5.

In the beautiful seashore area of the southwestern part of the country, in Palmar de Ocoa (which is included in Zone 6), we have Arturo HI8GB/6. He operates from his beach house during weekends. Arturo is a true DXer who speaks fluent English and also enjoys contests.

The eastern part of the country is Zone 7. Here we can find from 10 to 15 active ham-radio operators.

Zone 6 corresponds to the capital city which, as you would expect, holds the greatest number of ham operators even though the active ones number no more than 125. And Zone 9 contains only two operators, mostly active on 40 meters.

As it is clearly shown, the total number of active ham-radio operators in the Dominican Republic is close to 250, regardless of the 1500 or more that are listed in the *Callbook*. Due to this fact, HI is still considered good DX, especially on the 10-, 40-, 80-, 160-, and 6-meter bands, and it will be our purpose on these pages to keep you up to date with interesting information on when and how to make your contacts with HI in the different zones and on the bands that are more uncommon.

There is much more to come, but that will be in future columns from the Dominican Republic—the best well-kept secret of the Caribbean!

ECUADOR

B. Patricio Recalde S. HC2PP
PO Box 511
Guayaquil
Ecuador

Here is the inside view of what happened at the recent meeting in Cali (Colombia), attended by our delegate, Gustavo Crespo HC2NW. The sponsor was the Cali branch of Liga Colombiana de Radioaficionados and the meeting took place on the 50th anniversary of the foundation of the Liga.

On the first day, June 6, the five work committees were formed. Ecuador took part as secretary of the "VHF/UHF Satellites Commission." The meeting was held in CIAT, the Centro Internacional de Agricultura Tropical, and it was superb. There were simultaneous translations for all of the participants.

The commission in which Ecuador took part came up with the following:

- Frequency assignations in the new bands, and a compromise between governments which would allow radio amateurs to use the new allocations shortly.
- The procedure of issuing licenses should be standardized and the delegates will work toward that goal.
- It was decided that July 1, 1989, will be the deadline for governments to open up the new allocations.
- Peru proposed outlines of how to use the new segments.

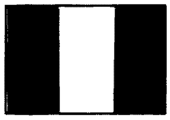
We should note here that most of the time, the decisions were unanimous.

A committee member from Japan gave a talk about the launching of the new JAS-1 satellite at the beginning of 1984 and explained how the funds were raised. One-third were donated by Japanese amateurs and the difference came from the government of Japan.

The committee also recommended that amateurs should give their QTH as standard calling procedure. If it is approved, we will say, for example, "This is HC2PP, latitude XX, longitude XX." It is a good idea, but it will take a while to catch on.

On the last night of the meeting, the Ministry of Communications gave away 500,000 postal stamps worth 12 Colombian pesos each, to commemorate the meeting of the IARU.

These highlights are a few words reflecting 800 pages worth of decisions at the meeting. The organization was fantastic, and there was always an HK radio amateur with every member or delegation.



FRANCE

Claude Guee F1DGY
11 Rue Emile Labiche
28100 Dreux
France

If you travel in France... try the 2-meter repeaters!

First of all, you have to ask for a French license. For this, apply to: DTRE-CGRP Service Radio-Amateur, 94002 Creteil (Cedex), France; phone (1)-569-96-20.

All of the information you need for a license will be sent to you. Don't forget, you have to submit your application early if you want to enjoy your FØ callsign.

Repeaters are very good companions for a trip in a foreign country. They can be very useful, too. At the very least, put an HT in your pocket and bring it along. Of course, it is better to have a car mounted with a 5/8-wave and 25 Watts (but keep customs in mind and have your bill of sale).

About 30 two-meter repeaters are located in "the Hexagon." They are in the upper part of the VHF band (144-146 MHz). Fifteen channels are scheduled, a little bit more than the IARU band plan calls for. To open a repeater, a 1750-Hz tone burst is required (you can also whistle). However, this tone burst is not necessary during the QSO. The time remaining after sending your callsign is sufficient. Transmit after the "K." Repeaters can be anti-chatter-protected. FZ1THF, for example, has a one-minute limit; it is very busy...

Some repeaters, such as F27THF, are equipped with voice synthesizers.

The shift is 600 kHz down, with a 25-kHz step between channels. Autopatch is not allowed, but on Tuesday evenings RTTY and SSTV are authorized.

Some home-brew equipment is heard on the air, but more often Icom, Kenwood, and Yaesu HTs are becoming popular for hikers and walkers.

Unfortunately, we also have intruders from time to time. They are called "Shaddock," from a famous cartoon on French TV.

Generally, few QSL cards are exchanged, except for FØ.

Between repeaters, there is no QRM when normal VHF propagation occurs. The purpose here is to have a low density of machines. Eventually, you may have the opportunity of using some simplex channels, such as 145.500, .525, .550, and .575.

English is not the mother language here, so contacts will be easier if you speak French—even a little. And while using other languages, speak slowly!

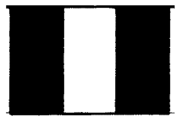
French 2m repeaters.

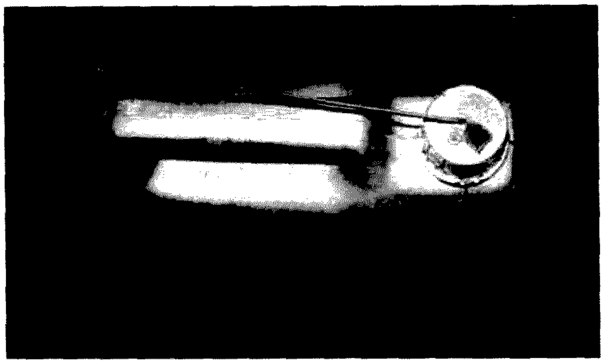


ITALY

Mario Ambrosi I2MQP
Via Stradella, 13
20129 Milano
Italy

The Italian QSL bureau has been reorganized and is now working at full speed. There is no backlog at the end of each month and the transit times have been substantially reduced. Cards are sorted by callsign at the QSL bureau and are bundled and shipped to the local radio clubs. In each of the clubs there is a manager responsible for local distribution.

Each member of the club has a box where he can find the incoming cards once a week during the meetings. There are about 200 of those clubs all around the



The oil-container transmitter case with antenna.

country; if you do not belong to one of them, you can have direct mail service to your address.

The biggest club is in Milano (more than 600 members). It is made up of a few rooms in a school building and has a conference room to accommodate all the members. The QSL service is now very fast, and from some random tests we have verified that it can take 3 or 4 months to receive a card from the moment you mail it to your bureau. But this is valid only if your correspondent does send you his card, which does not happen very frequently with US amateurs.

During the month of June, we had in Italy the first "League Clubs Contest." The participation was incredible in spite of the fact that this was the first edition. Being the contest manager, I was surprised to receive more than 3 feet of logs from 300 out of the 600 participants.

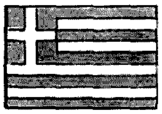
It has been a national contest and it will remain like that in 1984, but it could become international in 1985. The next contest will have an Icom HF transceiver as first prize and a VHF one as second prize. In the meantime, we will start a contest for SWLs that will have a general-coverage receiver for the top scorer.

A new award has been introduced by the ARI DX Blue Team—the IIA (Italian Islands Award). You need 10 points for it and you can get them by contacting stations in the Italian islands. It's easy to recognize them from the prefixes: IA1, IA5, IB0, IC8, ID9, IE9, IF9, IG9, IH9, IJ7, IL7, IM0, IS0, and IT9.

Islands with a local resident ham count 1 point; islands with no local resident ham count 3 points or 2 points (according to a long list that I can provide to anybody who needs it).

You can contact the same island on different bands and modes. There is an honor roll at 60 points and a 5-band endorsement for working 10 islands on 5 different bands. No need to send cards.

The cost is $8. The award is in full color on special paper and features an old map of Italy showing all the groups. All requests should be sent to ARI, Via Scarlatti 31, 20124 Milano, Italy, or to my address.



GREECE

Anastasios D. Panos SV1IG
PO Box 19063
Athens 11710
Greece

Repeater R1 at the top of Mount Parnis has been the target of some people for quite some time now. It is the most active repeater, especially during long weekends and holidays. A few days before Easter this year, a steady signal was at the input of the repeater, disturbing its normal use. After four consecutive days of night-only transmissions, we figured that the new beacon placed had a timing device that permitted it to work every evening. This made it difficult to trace, compared with the other two jamming beacons that had been on continuously in broad daylight.

The four 19-element yagis of SV1OE gave us an indication that the bug was placed close to the mountain. With fingers crossed, SV1NN, SV1NK, SV1RJ, SV1RP, and I started the fox hunt. SV1RJ borrowed a wooden broom handle that was converted to a 4-element yagi of his own construction—with fine results. The small convoy of three cars stopped at the parking lot at the foot of Mount Parnis. No signal was heard on our FM rigs and no signal was received by the SSB rig on our vertical.

We unpacked the "broom-yagi" antenna and there it was. A small signal appeared when the antenna was pointed to the casino/hotel at the top of the mountain. Enthusiasm made us forget the low temperature and gave us the courage to continue. Close to the top of the mountain and three kilometers before the casino, a strong signal blocked our receivers. As we got closer to the casino, the signal was weak so we decided to return to the earlier point. Strong indications again, but we could not pinpoint the bug.

A Yaesu FT-290 and an Icom IC-2E were in use at the time. By midnight, we were circling 200 square meters of a mountain with trees and rocks. The signal was strong with no antenna, but the rf was reflected by the trees, which made things difficult. The broom-beam worked again and gave us two indications. After walking some 30 meters on the road, we found the bug at the base of a tree.

It was a very sophisticated device contained inside a 4-liter motor-oil can. (See photos.) The antenna was on the outside with a photo-resistor that permitted it to operate only at night.

Authorities were not in a position to handle the matter at the time, so following the instructions of the president of our association, we removed it. After a good exam at my lab for fingerprints, it was forwarded to RAAG and placed with the other two beacons. The whole construction was made on a 3 × 5 cm PC board which had a 72.338 crystal. Ten D-size batteries in series powered the beacon, which drained 25 mA when in operation and 70 uA when off the air.

THE UK SCENE

I am finding writing this just a little difficult having returned only yesterday from a holiday in HB9 (Switzerland). It's not jet lag that is the problem (it being only a one and a half hour flight), but rather the general lethargy that sets in when the sun is hot and the beer cold!

All Swiss people are nice, and the small population of radio amateurs particularly so. The mountainous terrain of Switzerland makes local communications difficult and provides a perfect setting for a network of 2m repeaters. Most of the peaks have skiing centers with access via chairlifts and power supplies, so it is relatively easy to site a repeater in a good location.

I did not this trip apply for a reciprocal license largely because I did not wish to take any equipment with me. In retrospect, the 30 Sfr fee (about US$15) would have been well spent. During our trip we visited Geneva and decided to take a tour of the United Nations complex. Since I had my RSGB membership card with me and could therefore prove I was a licensed radio amateur, I decided to try to visit 4U1ITU. (This is available to any visiting amateur on proof of holding a current license.) The guides at the UN visitor center knew nothing of the station, although they spent some considerable effort trying to find some details. Eventually, I gave up and joined the regular sightseeing trip.

On the way back to town, I found the station. Well, almost, for on top of the ITU (International Telecommunications Union) building opposite the UN is a 3-element HF beam plus a mixture of VHF/UHF beams. So, on the next trip to Geneva, it's the ITU building that will be stop number one.

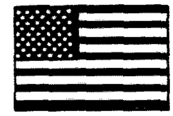
As usual on return from holiday, there was a mountain of mail. As well as some bills and a number of magazines (including 73), there were a few applications for the Cheshire Award which I manage.

The UK is divided into counties which correspond with something between counties and states in the US. The county of Cheshire is centered on county town Chester and is situated between North Wales and Merseyside. The Cheshire Award is available to licensed amateurs and listeners in three categories—Gold, Silver, and Bronze for 50, 30, or 15 points, respectively.

QSO points for US stations are 5 per CW/SSB contact, 10 per FM contact, and 15 per SSTV/RTTY or satellite contact. A QSO with Chester counts double points. Any readers interested in obtaining the Cheshire Award should send $3.00 to me with a copy of their relevant log extract (QSLs are not required). An application form with full details is available for $1.00.

I will return to the subject of UK awards later.

It seems no time since I started writing this column for 73 and yet this is already the sixth edition. You should by now have the measure of my approach to the column, but if you would like me to cover anything specific, please write to me. Remember, though, that there is a delay between writing and publication that makes coverage of topics such as contests rather difficult.



GUANTANAMO NAVAL BASE

James Sackey KG4SH/KA2SHH
Secretary/Treasurer,
Guantanamo Amateur Radio Club
PO Box 73
FPO New York 09593

The Guantanamo Amateur Radio Club (GARC) is alive and well at the US Naval Base, Guantanamo Bay. GTMO, as it is known in the Navy, the oldest US naval base on foreign soil and the only one in a communist country, is the assigned duty station of about twenty hams, ranging at present from a recently graduated and licensed Novice up to and including Extras.

As GTMO is outside of the FCC jurisdiction, the Commander Naval Base (COMNAVBASE) is authorized by the Department of the Navy, Navy Telecommunications Manual, to license and authorize amateur operations. To be licensed to operate from KG4-land, you must be stationed here, have in your possession a valid stateside license, and fill out the proper paperwork. Then the communications officer, under authority of COMNAVBASE, issues a 2 × 2 GTMO call. A ham can request any two-letter suffix.

Club president is Gary Murphy KG4DX, who, as you might expect from his choice of call, is very interested in working DX. Club meetings are held on the third Monday of the month at 2300Z, at the club station, located in hobbyland—the area of the base that houses the photo club, woodworking, and ceramics centers. Any ham visiting Guantanamo Bay is welcome to attend.

KG4AN, the club call, hasn't been too active recently since the Collins S-linear gear is on its last legs. The club is trying, through the Navy Special Service, to obtain funds for a new TR-7 and accessories. If the funds are available, the club might have the new gear on line by the end of this year.

This year, Tim Miller KG4TM/WB0RXX taught a Novice class that was both well received and successful. Of the seven who started the class, the only one not to be tested or licensed was a young boy who would rather play and be a distraction than study the code. The start of the classes was published in the base newspaper and broadcast over the local Armed Forces Radio and Television Service (AFRTS) radio and television stations on base. Among those who attended the class was a navy journalist who produced some of the announcements.

Not being content with only one ham class, KG4TM is again teaching prospective new Novices, so within the next months, listen for more KG4s on the Novice bands. For the information of newcomers to the ham ranks, KG4 counts as a country on the DXCC list. By the way, give new Novices a break—they will be scared silly when they first get on the air and are on the receiving end of a pileup...it's enough to make a guy wish he had studied something sane...like bomb disposal.

Speaking of DXCC, the GARC sponsors a Worked All GTMO award, which I will write about at a later date.

Continued on page 148

Make a Good L-Meter Even Better

Give the N5CC design a boost. Tack on this two-stage buffer and dodge those sneaky loading problems.

Carroll R. Bryan III WB1HKU/6
7311 Variel Avenue 4
Canoga Park CA 91303

Anybody who tried to run their W5JJ/N5CC L-meter (*73*, December, 1981) into their Max-50 or Micronta model 351 frequency counter probably got the same nasty surprise that I did—it didn't work. The display kept flashing, with a different reading each time, whether the counter was powered by a plug-in power supply or an internal battery.

The L-meter is a beautifully simple circuit, and I found it to be quite useful once I'd corrected the problem. The frequency counter is also a beautifully simple circuit, quite useful and relatively inexpensive. Anybody who owns one knows that he got what he paid for; part of what he didn't pay for, and didn't get, is a high impedance input and a buffering ten-to-one probe.

Using my scope, I saw that the counter input was loading the L-meter oscillator output way down and detuning it as well. Anybody who tried to make the connection work and who doesn't own a scope, now hear this: Pay off your analyst; it's not your fault; you've just got a little bit of work to do.

In my initial irritated reaction, I decided on some *QST*-style overkill. Perhaps a single buffer stage would do, FET or bipolar. But, I decided that if I was going to use this circuit as a bench instrument (it's sorely needed on my bench; have you ever tried to dip-resonate a ferrite toroid?), I wanted no sneaky loading problems to complicate things. Hence, the two-stage buffer with the "Are you really there?" 5-pF capacitor into the FET.

The figures tell pretty much the rest of story. I've included voltage measurements from my unit to aid you in bringing it up. Substitute parts anywhere you think you can get away with it, but don't be tempted to scrimp on the decoupling—mine motorboated at roughly 2 Hz until I filled in the missing capacitors. Any-

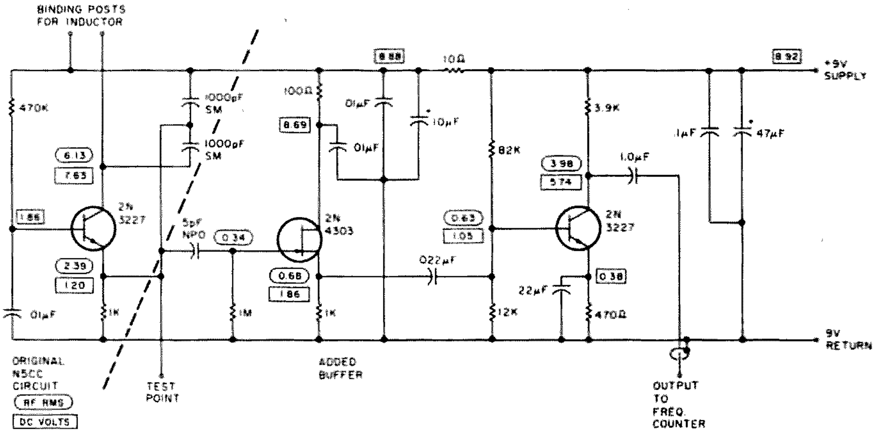


Fig. 1. Bipolar transistors can be 2N2222, 2N3904, etc.; FET can be HEP-801, MPF102, or another rf or general-purpose device. Dc voltages were measured with a 1k resistor in place of an inductor, using a Micronta/Sinclair DVM with 10-megohm input. Rf voltages were measured with a 100-uH Wee-Ductor inserted, using a VTVM-type rf probe into the DVM. My unit draws about 5 mA from a 9-volt supply.

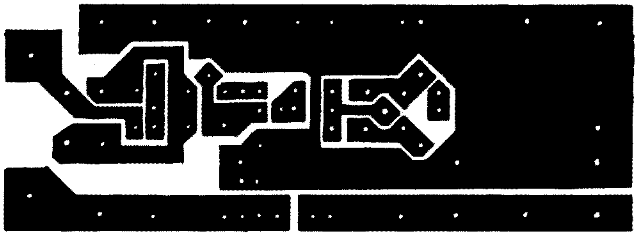

Fig. 2. Printed-circuit etch pattern. Drill holes are in a .1" grid; anyone using a drill/cut-and-peel technique, as I did, can use perfboard as a drilling template. With a little bit of fudging, the binding-post pads can be soldered directly to the wire terminals of a standard double binding post with ¾" pin separation.

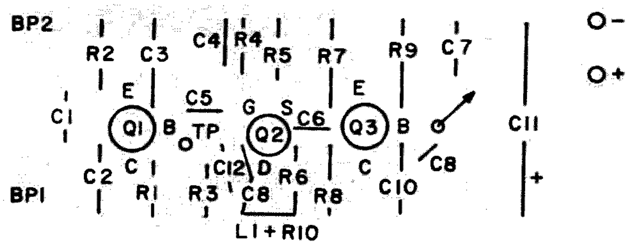

Fig. 3. Component layout. Use a piece of clipped lead for the test point. Check the data on your FET for pinout before installation.

Parts List

C1, C2	100-pF silver mica or polystyrene (NPO if available)
C3, C4, C10	.01-uF ceramic (.1-uF monolithic ceramic if available)
C5	5-pF NPO ceramic (silver mica is second best)
C6	.022-uF ceramic or polyester
C7	.22-uF ceramic or polyester
C8, C9	1.0-uF monolithic ceramic, ceramic, tantalum, or aluminum electrolytic
C11	47-uF aluminum electrolytic
C12	10-uF tantalum or aluminum electrolytic
L1	1 or 2 ferrite beads—FB43-101
Q1, Q3	NPN switching transistor—2N3904, 2N2222A, 2N3227
Q2	N-channel JFET—MPF102, 2N4303
R1	470k, ¼-W, 5%, c-c or c-f
R2, R5	1k
R3	100 Ohms
R6	82k
R7	12k
R8	3.9k
R9	470 Ohms
R10	10 Ohms
BP1, BP2	builder's choice—5-way binding posts, Fahnestock clips

body who's starting fresh on this circuit might find my PC pattern useful; refer to the original article by Carl Drumeller W5JJ for calibration information.

My thanks to William Huffman N5CC, whose design is coming in mighty handy at my station. ■

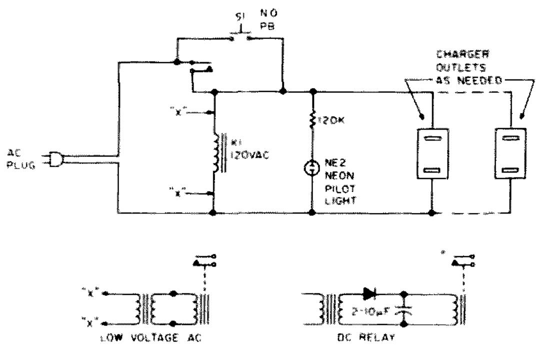
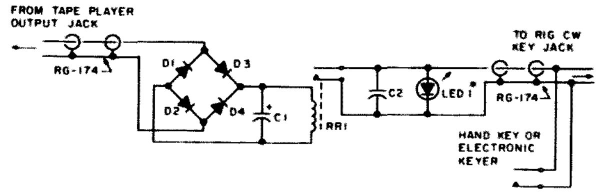
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

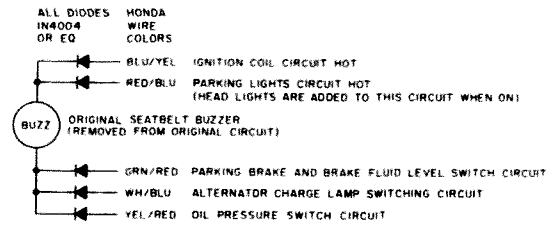
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



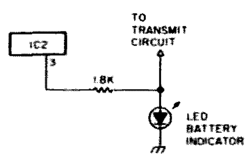
LIMIT YOUR CHARGE TIME: This circuit can be used with a 24-hour timer to limit the charging time of your batteries. To use, set a timer to have an on time equal to the charging time of your batteries. Plug the timer in and plug the circuit into the timer. Pushing switch S1 will energize the charger outlets for as long as the timer stays on. After turning off, the circuit will not reactivate until S1 has been pushed. The relay is a 120-V-ac unit, but a low-voltage ac relay can be used with a suitable transformer.—George Lundberg WA9JBH, Oak Forest IL.



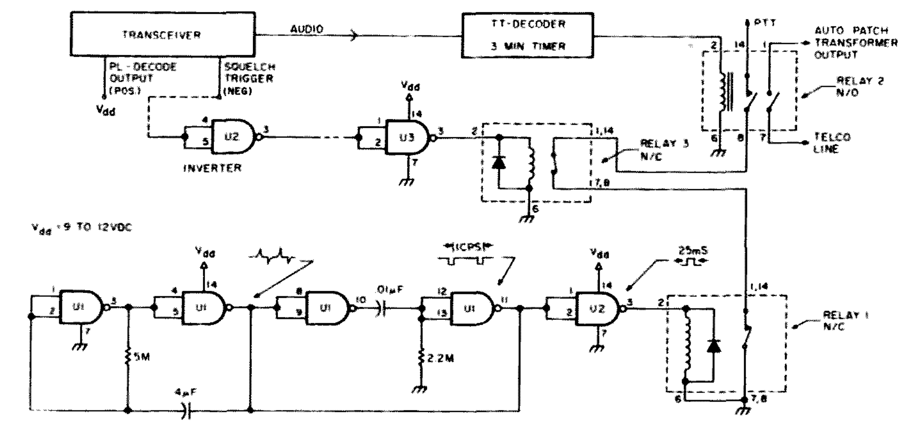
INEXPENSIVE MEMORY KEYER: By passing prerecorded audio from a tape player through a full-wave bridge rectifier, the audio is converted to on-off pulses which key the transmitter through a reed relay. Use a code-practice oscillator or sidetone generator to record the message. C1 holds the voltage across the reed relay (RR1) for the duration of the pulse. For use at speeds over 20 wpm, you will have to experiment with the value of C1. Also, be sure to record your message with enough voltage to operate the coil of RR1. D1-D4 are the rectifier diodes; C1 is a 200-uF 15-V electrolytic capacitor; C2 is a .01-uF disc capacitor; and LED 1 is an optional LED visual indicator. —William Edwards N8ARW, Niles OH.



IDIOT BUZZER FOR THE 1978 HONDA CIVIC: This circuit uses an existing seat-belt buzzer to indicate a fault condition in a variety of automobile systems. The buzzer will sound whenever the brake fluid level is low, when the oil pressure is low, when the alternator is not working, or when the parking brake is on. However, either the ignition or the headlights must be turned on for the circuit to operate. Correct wires must be found by testing as well as by color codes, because Honda uses the same colors for more than one circuit. Cars using idiot lights for the temperature instead of a gauge may include this feature by adding one more diode.—Franklin E. Swan W9SIA, Oak Forest IL.



RECEIVE INDICATOR FOR ICOM HTs: Use the transmit/battery LED to tell you when your 2AT, 3AT, or 4AT is receiving a signal. Connect a 1.8, ¼-W resistor between pin 3 of IC2 (the audio ouput amplifier) and the anode of the LED. IC2 is a single-in-line package located next to the speaker hole on the receive PC board at the front of the rig. Pin 1 is the pin toward the center of the board. Connect one lead of the resistor to the third pin and extend the other lead with a short piece of insulated wire. The wire should be soldered to the pad where R56 connects to the wire going to the LED. When the squelch breaks, this modification will cause the LED to light, but transmit operation will not be affected.—Robin Rumbolt WA4TEM, Knoxville TN.



SIMPLEX AUTOPATCH RECEIVE WINDOW: This circuit will provide a 25-millisecond window once per second. It is especially suited to making your own simplex autopatch system. U1 and U2 are 4001 quad, 2-input NAND gates, Radio Shack number 276-241. U3 is a 4093 quad, 2-input NAND Schmitt, Radio Shack number 276-2493; relays 1 and 3 are Magnecraft DIP type W217 DIP 19 SPST-NC, and relay 2 is a Magnecraft DIP type W117 DIP 11 DPST-NO. Both types are available from GSN Electronic Components, 91 W. Passaic Ave., Rutherford NJ 07070.—David C. Smith WB2EPZ, Jupiter FL.

MULTI-PURPOSE CONDUCTIVE TAPE: The copper-foil tape used by stained-glass enthusiasts makes an excellent material for rf-proofing enclosures, custom-shaping ground planes and making PC-board layouts. The tape's adhesive is nonconductive, so when you are joining two pieces of tape, make sure you solder the joint. This copper-foil tape is available in a variety of widths at most crafts stores.—M. Rosenzweig WB2BOM, Steamboat Springs CO.

Ironclad Repeater Control

With 12 outputs and tamper-free access, you can keep a firm grip on your repeater's operations. And this circuit keeps the price from getting out of hand.

My requirements in a tone decoder were to control a 220-MHz repeater system with an autopatch, amplifier, and several other functions.

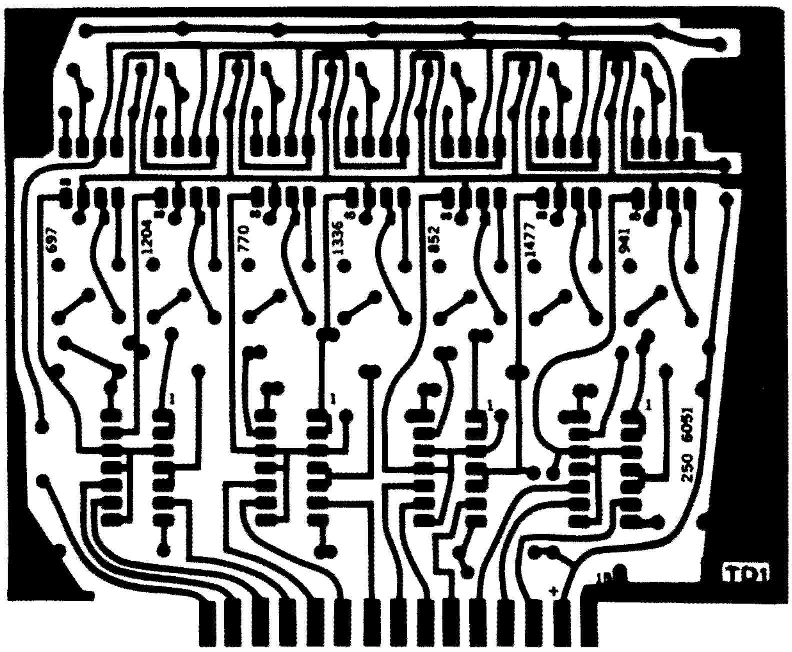

Fig. 1. Tone-decoder PC board, foil side.

The final design of this dual-tone, 12-output control board is used for selectable tone squelch, station identification, amplifier ON/OFF, and many security functions such as repeater and autopatch access through an access-control board requiring three-digit commands.

The tone-decoder board (TD-1) is constructed on a standard plug-in card and utilizes the type LM567 phase-locked loop and the National-type CD4025BCN Cosmos logic gates to detect audio tone pairs and provide 12 outputs.

The PLL's free-running frequency is set by means of potentiometers R8 through R14, in conjunction with resistors R15 through R21, and capacitors C17 through C23. In the presence of an audio tone of proper amplitude (20 to 200 mV/rms) and frequency, a

Tone-Decoder Parts List

R1–R7	4.7k Ohm
R8–R14	5k Ohm
R21–R28	10k Ohm
R15, R17, R19	8.2k Ohm
R16, R18, R20	3k Ohm
C1	22-uF electrolytic
C2–C8	1-uF electrolytic
C9–C15	2.2-uF electrolytic
C17–C23	.1 uF
C16	6.8-uF electrolytic
C17	.68 uF
U1	5-V reg.
U2–U8	PLL-type 567
U9–U12	Triple NOR 4025B
PCB	TD-1

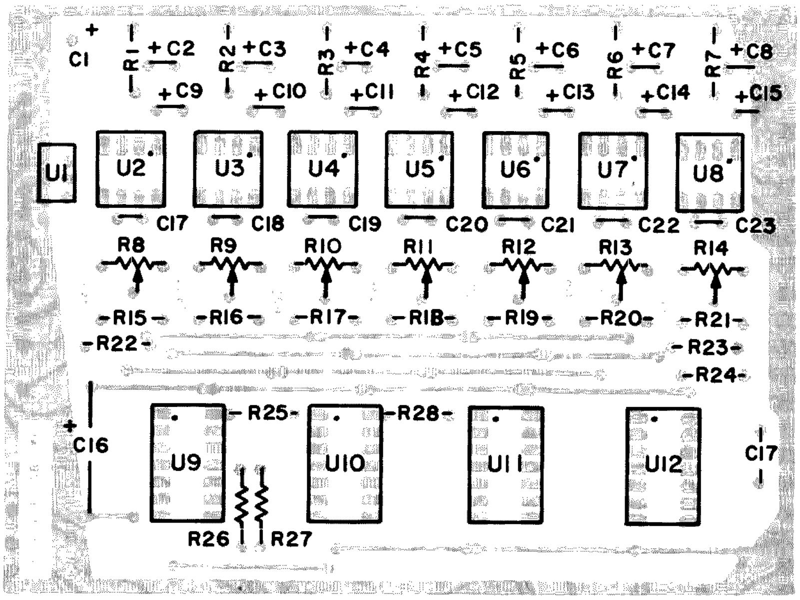

Fig. 2. Tone-decoder PC board, component side.

PLL will lock to the incoming signal after a variable number of cycles, depending on the amplitude and phase relationship at the moment the tone starts. When the PLL locks, its output changes from a high to a low condition (pin 8 of the 567s).

Pairs of one high- and one low-band tones will activate two of the decoders, which will result in low outputs. One of the logic gates in the 4025 integrated circuits will detect the combination and produce a high output. The board is intended to work with power supplies from 7 to 15 V. The voltage regulator, U1, provides 5 V for the 567 ICs. If 5-V operation is required for all the board, U1 can be removed and a jumper used to connect the 12- and 5-V lines together. Three input NORs are used for lower output impedance and circuit layout symmetry.

Testing

Using a frequency counter, check pin 5 of each 567. Set the free-running frequencies for the marked values ±5 Hz by using the corresponding potentiometers. 20 mV/rms of each tone should be sufficient to lock the PLLs.

If a frequency counter is not available, a tone encoder can provide the necessary test tones. The amplitude used should be reduced to the point where locking takes place (close to 10 mV or so), in order to guarantee the smallest bandwidth to the decoders and the best setting.

I am sure you will find many station-control applications for this decoder. A touchtone™ pad near your operation position can consolidate commands for automatic ID transmissions, changing antennas, or starting up the coffee pot.

The PC layout shown is a double-sided board. Parts for this project are available through many sources or you can buy the entire TD-1 board, fully assembled and tested, from Frank Kalmus WA7SPR, 7016 N.E. 138th, Kirkland WA 98033, for $39.00, postpaid.

Access-Control Board

This access-control board

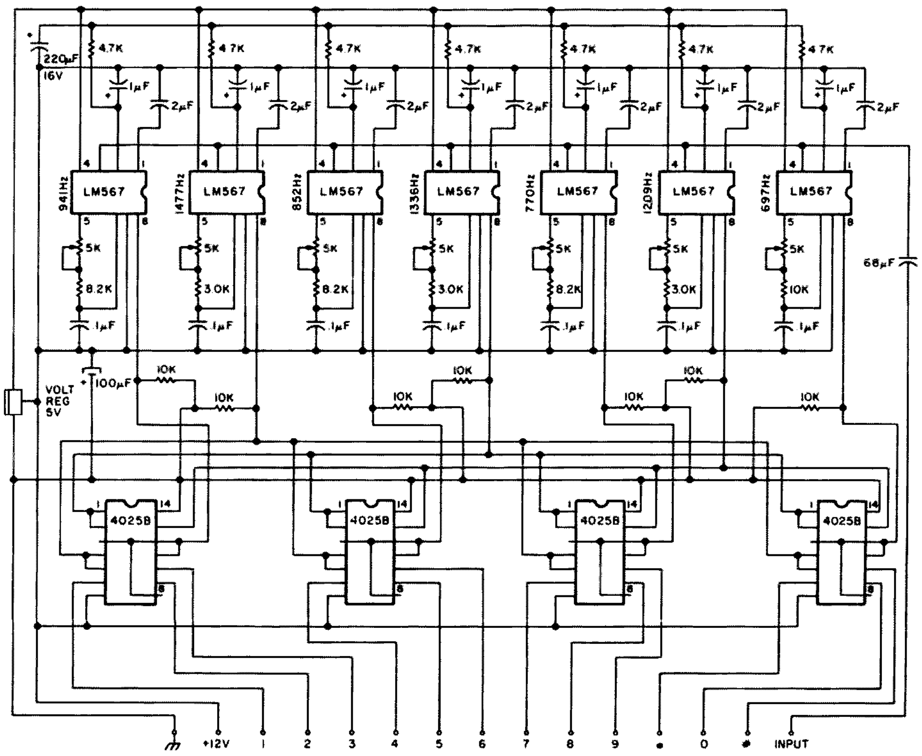

Fig. 3. Tone-decoder schematic.

will provide you with an exclusive access-security system. The access-control board is a logic unit designed to be used anywhere that sequentially-coded remote control is needed, i.e., with your tone-decoder board. The access-control board will provide five independent, three-digit coded circuits to use for repeater control, two-way radio systems, etc.

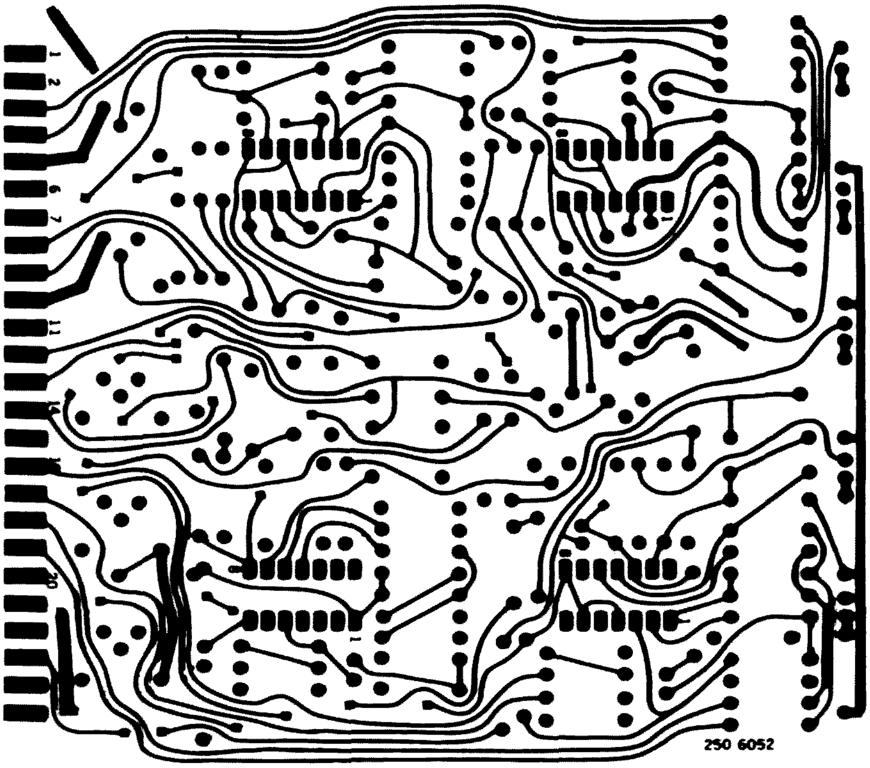

Fig. 4. Access-control board, foil side.

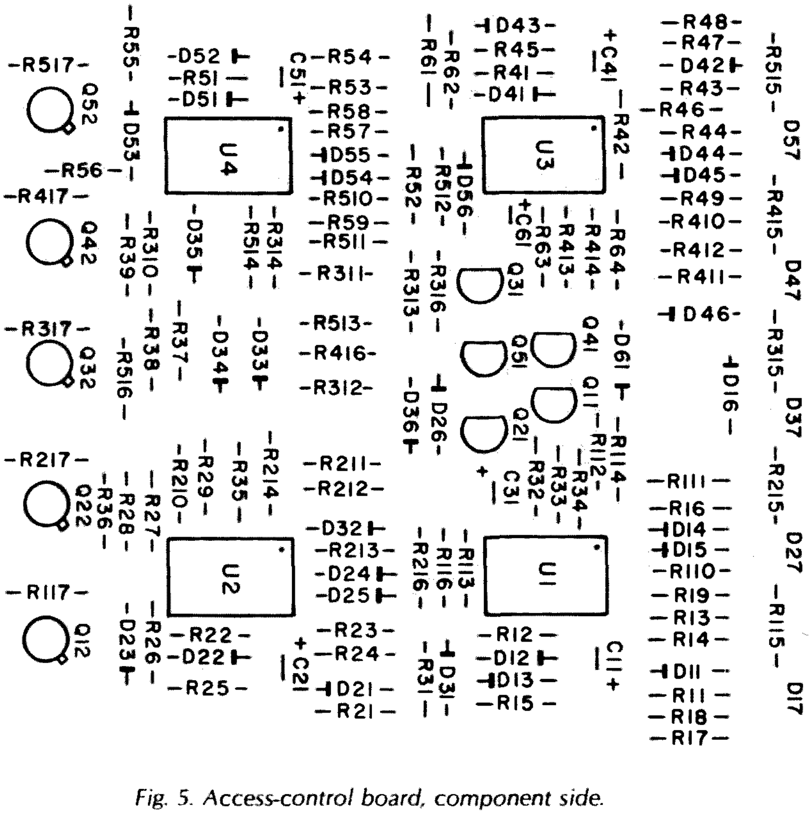

Fig. 5. Access-control board, component side.

The access-control board works with power supplies from 4 to 30 V and interfaces across any existing logic or analog system. Each of the five channels has four inputs. When three of the inputs are driven high in the proper sequence and within the preset time, the output will go ON or OFF, depending on the input used in the third place. In other words, the third and fourth inputs decide the output condition when inputs one and two have been previously activated.

The timing section in each channel defines how much time can be used to perform the complete sequence. The power ON reset is built-in, and a clear line is available to disable all channels at any time, if needed. Five LEDs are used to monitor the output condition of each channel.

The following theory of operation refers to one of five identical channels. When activated, the first stage works as a timer and enables the second input. The input threshold is roughly (Vcc/2 + .7)V. Once the input is above the threshold level, the output of the comparator goes high and enables the input of the second stage. At the same time, capacitor C1 is charged through R2. When the input goes low, C1 starts discharging through R2 and holds the comparator high for the timing period (recommend 2 seconds). The threshold of input 2 is Vcc/2. Once this threshold is overcome, the comparator goes high and diode D3 will hold that condition as long as the first comparator is also high.

The second stage gates both inputs of the third

through D4 and D5. This final comparator is designed in a bistable mode obtained by using proper feedback (R11 and R13) and input isolation (R9 and R10).

The transistor, Q1, drives the monitor LED which lights when the output is ON. Q1 is the output transistor which is open when the output is high and conducts in the low condition. The circuit operates anywhere from 4 to 30 V. Above 15 V, it is recommended that the value of R13 be increased in order to keep the LED current below 50 mA.

Testing

Apply 12 V to the board (all LEDs will remain OFF). Using a jumper, put 12 V sequentially in inputs 1, 2, and 4 of one channel, not taking more than approximately 2 seconds for the process. The LED will light after input 4 is activated.

Repeat the procedure, but ending with input 3 (the LED will shut OFF). During the timing period, the output can be switched ON and OFF by alternately touching inputs 4 and 3. Using a voltmeter, check the output voltage in the high (Vcc) and low (ground) conditions.

Repeat the same steps with the remaining four channels.

To check the "Clear" line, ground it using a jumper. All channels will shut OFF as long as the ground is present, whatever the input conditions are. ■

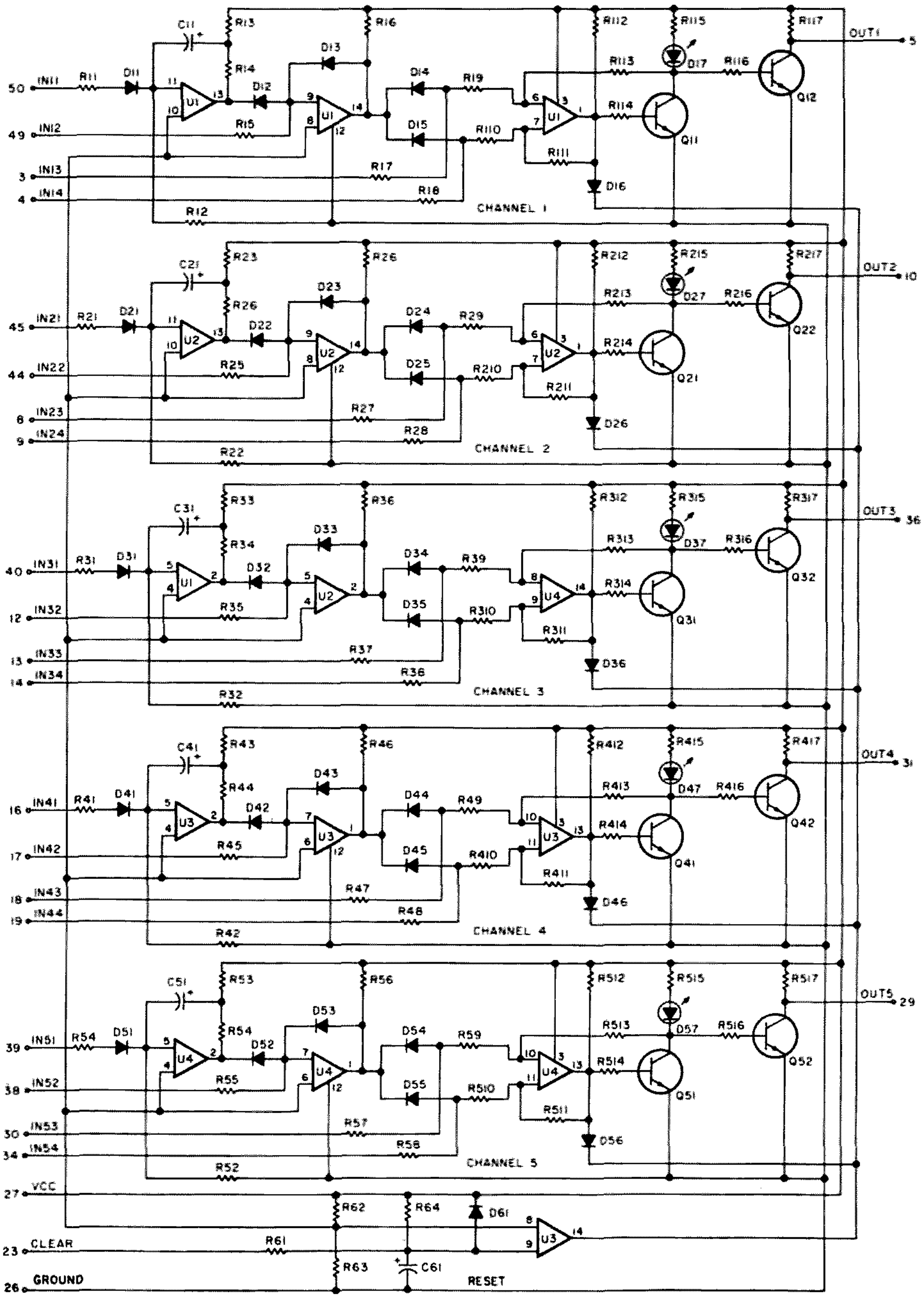

Fig. 6. Access-control board schematic.

Access-Control Board Parts List

Reference	Qty	Description
R15	5	Resistor, 330-Ohm, ¼-W, 5% carbon

XU KAMPUCHEA

Late this past summer, several stations appeared on the amateur bands from Kampuchea (formerly Cambodia). These amateurs were operating under all international amateur-radio regulations, from within the internationally recognized borders of that country. Their licenses were granted directly by the prime minister of the government. In fact, the callsign of the first amateur station, XU1SS, reflected the initials of the prime minister, Son Sann. Yet the chances of contacts with XU1SS counting for DXCC credit are slim.

The XU1SS and other XU callsigns generated an understandable amount of commotion on the DX bands. Understandable because no legitimate Cambodian station has been on the air in many years—since the last Americans left in the early 70s. But this excitement is likely to be to no avail, since the XU1SS QSL cards will probably suffer a fate similar to those of XZ5A: as curios, not DXCC counters.

The amateur-radio operations in Kampuchea do bear a striking similarity to those in nearby Burma. The XU1SS operations were conducted under the auspices of the KPNLF (Kampuchea People's National Liberation Front), which is the "exile" government of Kampuchea. The KPNLF is the leading member of a loose coalition of political parties called "Democratic Kampuchea." Democratic Kampuchea is the officially recognized government of the country, even though they physically occupy one tiny corner of the country.

The socialist Kampuchean government, which gained power through force of arms, lacks international recognition (by non-communist countries). The Democratic Kampuchea coalition retains the United Nations seat. But for "practical" purposes (as opposed to diplomatic purposes), the socialists are in charge. And they don't like amateur radio. So where does this tangled web of international politics leave XU1SS? Probably out in the cold.

You can't fault the XU amateurs for trying. The amateur operation is part of the international support for the many thousands of Cambodian refugees near the Thai-Cambodian border. Each day many volunteers from all over the world, including several Japanese amateurs, crossed the border with day passes, to aid in the refugee work. These Japanese hams set up an amateur station in Ampil, near the Thai border, on aptly named "Ham Avenue." The Japanese hams were restricted to daytime operation, because of their volunteer border passes, but they trained some native operators for late night contacts and to continue on the air after the Japanese returned home.

So here we have a bunch of hard-working volunteers, setting up and training hams in a much-sought-after country, working with the direct support of that country's president, and it still doesn't count for DXCC. How did we get into this ridiculous position?

We have to go back more than 10 years to come to the root of the problem. Before Don Miller got caught lying about his operating location, the ARRL DXCC branch generally assumed an amateur operation was legitimate. In other words, the operation took place from within the "country" indicated and was not against the law of that country. But after the Don Miller lawsuits, the League's DXCC gang started getting fussy about proof that the operation took place as claimed. And to avoid offending any potential votes at the WARC international frequency-allocation conference, the DXCC gang tried to avoid giving even their limited "recognition" to amateur operations that did not have the full support of the country's government. At the same time, popular sentiment has led to a change in the rules for defining what is a DXCC "country," so that individual rocks and islands don't wind up as "countries," as we had with St. Paul Island off Nova Scotia, for example.

That attitude may have been a good idea at the time, but its continued application has stifled DX. The flood of new and changing countries has slowed to a mere trickle. The fine band conditions of the past few years have brought up the DXCC totals of many amateurs to the point where new countries to work are essentially nonexistent.

This problem is not due to any lack on the amateur's part. Lack of courage in the face of unknown dangers is no obstacle, as we saw in the ill-fated attempt to activate the Spratly Islands. Nor is expense an overwhelming factor, as the DX community provided tens of thousands of dollars of support to several major DXpeditions recently. Nor have all the older DXers gone on to other activities. The XU stations generated good pileups, and many seldom-heard callsigns were in there calling. So the DXers are listening; they just don't hear much that excites them.

Japanese amateurs have been instrumental in restarting amateur radio throughout Asia, including Kampuchea. Kan Mizoguchi JA1BK was a key figure in the activation of China BY1P. (Photo via The DXers Magazine)

JA1BN's impressive shack.

A Modest Proposal

So what can we do to inject some new life into the DX world and reward the efforts of these hard-working and well-meaning amateurs, such as the XU gang, without opening wide the gates to encourage potential cheating? One way might be to initiate a "Wild Card" for DXCC. The ARRL DXCC group would have a middle ground, a third alternative to the present "accepted for DXCC credit" or "not accepted." The third alternative would be granted to operations such as the XU1SS effort, that is, to well-meaning amateur operations unquestionably within the borders of the country claimed but unable to meet full DXCC requirements. Other types of amateur operations which might fall under the same category would be times when the local authorities give verbal permission for amateur operation but won't grant a written license. Or an effort such as the 1S1CK DXpedition into the Spratly group. Each DXer would be allowed one Wild-Card confirmation each year, from the ARRL's list of eligible Wild-Card operations.

This proposal leaves the majority of the DXCC rigmarole unchanged while providing at least some incentive for amateurs on both ends of the pileup to keep trying. Any change in Honor-Roll standing or relative positions would be gradual, over a period of years. Longevity will continue to be the single most important possessior for Honor-Roll status, as each year of DX activity means another potential Wilc Card.

The DXCC branch should welcome the additional alternative, as it gives them ar "out" in otherwise sticky situations. Fo example, when we wanted to win Japan's support for the IARU's WARC band pro posals, the ARRL made 7J1RL, Okina Tor Shima, a separate DXCC "country" and later had to delete it. How much simpler i would have been to make 7J1RL a Wilc Card! Or take the case of 4U1UN, where the League either had to eliminate 4U1ITU, in Geneva, or say a separate "country" existed in downtown Manhat tan.

Will the League go for this idea? New ideas have not had a good history at 22 Main Street, especially around the D) desk. But DX sentiment is rising for some changes, serious changes, in the DXC(rules and administration. Some other pos sibilities are: scraping out the system and replacing it with a totally new one (ove the dead bodies of many hundreds of Hor or Rollers and near-HR DXers), or simpl granting "DXCC-Counter" status to an well-run DXpedition, regardless of the lc cation. Dry Tortugas? Water Island? Prib lof Islands? The League could defin guidelines for *how* the DXpedition opera ed, without regard as to *where*. Fred Las

K2TR would return to the sanitary landfill in the middle of Lake Ontario, where he activated WD2UMP back when the FCC issued such calls. And why not? Is this any more absurd than the system we have now? At least it would be a lot more interesting!

NOTES FROM ALL OVER

Tom Gregory TU2NW is up and running in Abidjan, Ivory Coast. Tom runs a Kenwood TS-830S with remote vfo into an Alpha amp. His antenna farm includes a KLM KT-34A at 60', a multiband vertical, and wire antennas for the lower frequencies. Look for Tom around 28555, 21300, 14155, 7070, and 3795 on SSB, and 20 kHz up for CW contacts. Tom likes contest operations and is looking for donations toward a contest keyer. Donations and QSLs must go via Mike Hayden AK3F, PO Box 573, Gettysburg PA 17325.

Don Mears KX6QO is trying to find former KX6 (Kwajalein) amateurs—both residents and DXpeditioners. Don hopes to forward some of the thousands of undeliverable QSLs piling up on Kwajalein. If you ever operated KX6, send your address to Don at PO Box 793, APO San Francisco CA 96555. Don also reminds DXers that KX6 calls with a single-letter suffix (KX6A–KX6Z) are in California, *not* Kwajalein.

Vic Rivera ZK1CG, in the Cook Islands, says he is the QSL manager for WA0QZW/6, one of the very few DX QSL managers for a stateside station! (Box 618, Rarotonga, Cook Is.)

Also out in the Pacific, Dave Patton KJ9W is knocking around the Guam area, especially in contests with Tom N7DZE. Dave hopes to hit spots such as CR9, DU, VQ9, 9V1, KH1-0, and KC6, mostly CW. QSL any contact with Dave via K9XR.

New QSL Address

BV2A—Charlie Moraller K2CM, Rt 1, Box 43, Grantsville WV 26147.

Jan Weaver N7YL handles QSLs for the following stations: T32AB, T3LAB, T3LA, VR3AR, W1DDV/C6A, C6ADV, and KA3BUJ/8R1 (1981-2). She also has logs from 1976-9 for VR1AG, VR1AF, FK8BG, and VK4FJ/LH. Jan's new address is: 2195 East Camero Avenue, Las Vegas NV 89123.

Follow-Up from Previous Columns

I asked the origin of a very funny "letter to an insurance company" bit (July). Three widely scattered DXers set me straight. The piece was part of the repertoire of Gerard Hoffnung, an English musician and humorist. Thanks to KF4AI, VE7BS, and N1BEF for the information.

Rich Kingston 7P8BC asked me to clarify some of my March column on Lesotho. Rich supplied information on only the amateur-radio activities in Lesotho; I dug up the background on the country myself. Rich writes, "Lesotho has a great potential as a tourist area with some of the most spectacular scenery in the world."

REVIEW

SHORTWAVE HOBBY EQUIPMENT REVIEW

The *Shortwave Hobby Equipment Review* is published by the International DXers Club of San Diego and is a book aimed at providing information concerning shortwave receivers and accessories to the shortwave listener. The *Review* is made up of reprints from the club's monthly bulletin and is updated by yearly supplements and quarterly updates. It's published in loose-leaf form so that updates can be added easily.

This book is unique because it attempts to deal with the technical area of receiver performance in a decidedly nontechnical way. These reviews, some written by members of the club and others reprinted from both domestic and foreign shortwave magazines, don't read like those in QST, or even in *CQ*.

They are more properly called user reports, and because several reports from different users are included for the most popular receivers, the book gives a good overview of the good and bad points of the equipment. There are some technical reports of receiver performance included, always with the editor's caveat that "I don't know what this means, but maybe you do."

Along with reviews, the *Review* contains modification hints (generally nontechnical), rumors about new receivers, editorials on receivers and antennas, and the random ramblings of Larry Brockman, the president and spiritual leader of the club. The book also includes a section on TTY "listening."

Although the emphasis of the book is on current shortwave receivers, some ham equipment with general-coverage capability is included. There is a fair amount of material covering vintage receivers, giving opinions as to good and bad models, as well as modification and spare parts info on some of the more popular boat anchors. Any book that tells where to find spare ballast tubes for an R-390A can't be all bad! Receiver preamps and preselectors also are well covered.

The non-review parts of the *Review* are in some ways the most interesting. Larry Brockman is apparently one of those fellows who's done a little bit of everything and has strong opinions about anything. I think he's a bit like Wayne Green—you either like him or hate him, but either way he's fun to read.

I don't think I can recommend this book for the ham with no interest in shortwave (as opposed to ham) receivers. There's just not enough material pertaining to ham equipment to justify the cost. If, however, you do play SWL and are interested in what the market has to offer in that area, the *Shortwave Hobby Equipment Review* may be the ticket.

For further information about the *Review* and about membership in the club, contact the *International DXers Club of San Diego, 1826 Cypress Street, San Diego CA 92154-1154.*

John Ackermann AG9V
Green Bay WI

THE ICOM IC-751 HF TRANSCEIVER

Considering the state of the integrated-circuit art, I suppose it was inevitable that an "amateur" transceiver of this complexity would be made available to hams and shortwave listeners. The Icom IC-751 HF transceiver is an incredible package of versatility, accomplishing in one unit what a few years ago would have taken an outboard microcomputer in addition to a transceiver.

As Table 1 shows, the IC-751 is really a complete amateur-band-only (including WARC bands) transceiver *and* an all-mode general-coverage receiver. In addition to what you might expect—CW/SSB/AM capabilities—there are also FM and RTTY modes along with 32 frequency/mode memory and scanning facilities, two vfo's, filters, noise blanker, passband and notch tuning, rock-solid stability, and even an optional synthesized voice to inform you of your frequency. This last feature is particularly intriguing for the visually impaired because frequency determination is probably the hardest parameter to represent non-visually.

For this review, I received the 751 and the optional IC-PS15 outboard power supply. There are a lot of options to come, says Icom, including internal power supply, external frequency controller, more filters, and other goodies. I carefully unpacked the two boxes and found that Icom had done an excellent job of protecting its products against shipping damage, and everything, including the documentation, was sealed in plastic. The 32-page instruction manual package also included some functional block diagrams and a complete schematic: a two-sided fold-out that requires a Sherlock Holmes type magnifying glass to read. But it's nice to know you have a chance of tracking something down should (dare I say it?) anything go wrong.

Band	Frequency Range (MHz)
160	1.800.0— 1.999.9
80	3.440.0— 4.099.9
40	6.950.0— 7.499.9
30	9.950.0—10.499.9
20	13.950.0—14.499.9
18	17.950.0—18.499.9
15	20.950.0—21.499.9
12	24.450.0—25.099.9
10	27.950.0—29.999.9

Table 1. Amateur-band coverage.

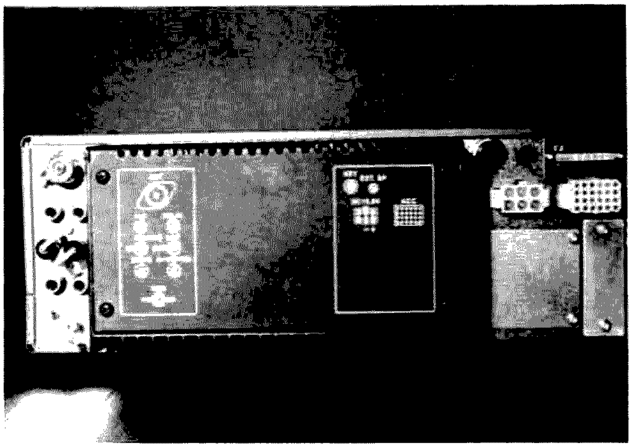
The only connections required are mike, key, antenna, ground, and power cable to the separate supply. The power supply then plugs into 115-V-ac power, and that's that. Also included is a hefty dc power cable should you decide to run the 751 directly from 12 V dc. But if battery power is contemplated, don't forget that at 200 Watts input you'll need 16–18 Amps at 12 volts.

As I perused the instruction manual, I soon found that this wasn't the sort of equipment you just intuitively know how to operate; there are over 50 operator controls, some of which function differently

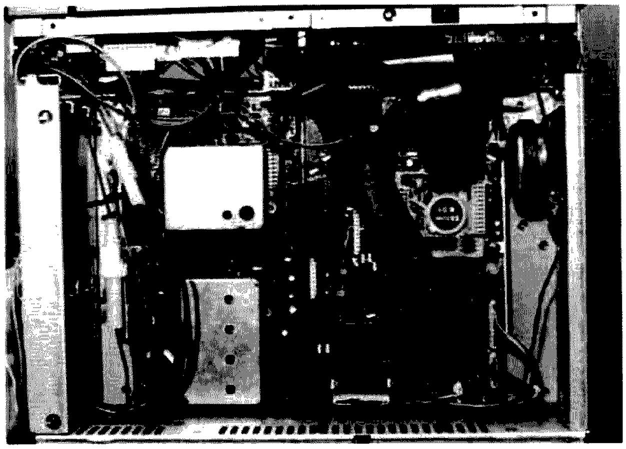
Mode	Display
USB	9.997.0
CW/RTTY	9.999.4
LSB/AM/FM	10.000.0

Table 2. 10-MHz WWV carrier frequency as displayed according to the scheme shown here.

The Icom-751 HF transceiver.



The back side of the 751. The legends identifying the connectors are much easier to read than the usual stamped-in letters. The vertical plate in the lower right is rumored to someday soon hold access to the microprocessor's address and data lines.



The underbelly of the 751. The optional internally-mounted 115-V-ac power supply mounts on the bottom cover and protrudes into the surprisingly open space.

depending on the position or setting sequence of others. But after a time of reading and experimenting and operating, most things began to make sense. I say most things because in spite of the 751's attempt to be the last word, it has some peculiarities worth mentioning. More on those later.

The 751 accommodates both the Icom IC-HM12 electret hand mike with fingertip frequency-scanning push-buttons and the IC-SM6 stand microphone. Both are wired for the 8-pin connector on the front panel. Included are a built-in speaker with very good intelligibility and a two-detent headphone jack for speaker, speaker/phones, or phone-only operation. An external speaker jack is also provided that disconnects the internal speaker when plugged in. Audio is clean, crisp, and very strong, and intelligibility seemed best to me with the TONE control at full treble.

My initial operation was with the general-coverage receiver because I figured I couldn't hurt anything by just listening. When you turn on the 751, there's a pleasant silence and the multi-purpose meter illuminates. The complex digital display is blanked for a second or two, but then with a definite relay click, the red and blue display comes to life.

The heart of the 751 is digital, including a microprocessor, and the logic is arranged so that on power-up the complex display indicates that the transceiver is in amateur (HAM) or general-coverage (GENE) mode (depending on how you last left it), vfo A is selected, and memory-channel 01 is queued up first. Ham-band coverage is confined to the band segments shown in Table 1, but general-coverage reception is continuous from 100 kHz to 30 MHz.

Operation

Suppose you wanted to check out the gang on 21.380. If you've previously programmed, say, channel 03, then you touch the VFO/M push-button and you're there. Along with the frequency, the digital display shows that you've automatically been put in USB, too. If no one is there and you want to try a favorite haunt on 15m CW, perhaps 04 in memory, a very slight twist of the main-tuning control clicks you instantly into 21.016 in the CW mode. No other controls need be touched. If 15 is dead and you want to try 40, a programmed 05 (or any other location up to 32) and another main-tuning-control twitch puts you there, along with auto conversion to LSB. A function switch enables you to change to USB or other modes if desired.

The 751 includes automatic carrier offsets for all modes—as shown in Table 2. So, when you change modes, the built-in calibration to WWV always reflects accurate carrier (or suppressed carrier) frequency. This is one of the little quirks that is kind of hard to get used to. This means that WWV on 10 MHz is displayed as 10.000.0 even when you know you are tuned off carrier frequency for AM reception. As far as mode selection goes, the amateur conventions of LSB on 7 MHz and below and USB from 10 MHz on up are followed.

If for some reason you have used up all 32 memory channels and would like to check propagation on any or all the ham bands, all you need to do is touch the BAND select push-button and turn the main-tuning control. The 751 is programmed to start near the bottom of each band, the exact location of which depends on operating mode—as shown in Table 3. A second touch of the BAND select push-button allows you to tune freely throughout the band.

When you reach, for example, the top of a band, the 751 jumps back to the bottom of the band. Similarly, when you reach the bottom of the band, the next step is back to the top of the band. When you decide to try the next higher or lower band, depress the BAND select switch and rotate the main-tuning control to click into the next band. For general-coverage applications, a similar sequence occurs, but in 1-MHz steps.

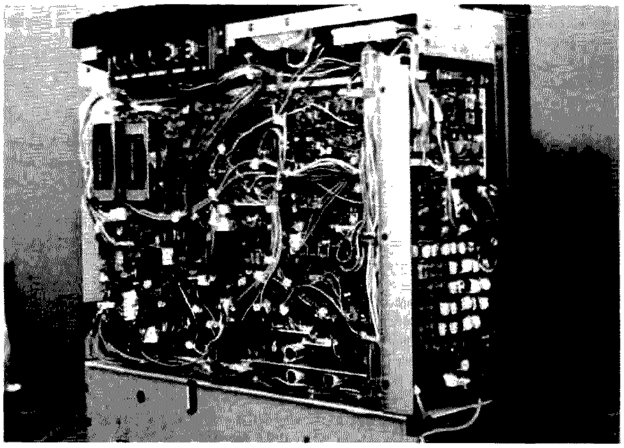
After you've made your coarse frequency selection via the BAND select push-button, you have your choice of several tuning-rate options. Slowest is about 2 kHz per rotation of the main-tuning control. If you physically tune faster, that is, spin the dial with a flick of the wrist, the tuning control automatically shifts into a faster rate—about 10 times as fast. Depressing the tuning rate push-button (labeled T S) really shifts tuning into warp drive—about 200 kHz per rotation. If all this sounds a little formidable, don't despair. You catch on rather quickly and it gives you enormous band, frequency, and tuning agility.

Because the front panel is already so full of controls and push-buttons, I guess Icom had to delegate some functions to a different geographical location—in this case, a small auxiliary panel on top of the transceiver directly above the display. Here you'll find a preamp/attenuator switch that lets you choose among straight-through, 20 dB of attenuation, or 15–20 dB of gain, as near as I could tell. The instruction manual doesn't say what the gain is, but the preamp does work well with little extra noise added in.

Also located on top are the MARKER switch and CALIBRATOR control. Because the internal logic of the 751 automatically compensates for carrier position and a central synthesizer is common to all bands, you need only dial in WWV on AM, set the display at 10.000.0 MHz, for example, and with the MARKER switch on, adjust the CALIBRATOR control for zero beat.

Unfortunately, I found this very difficult for several reasons. First, if the WWV signal is weak or exhibiting a moderate amount of QSB or flutter, the calibrate signal strength overpowers it so that it's

The non-ergonomic top-panel controls. Perhaps they are recessed because Icom knows hams love to stack equipment to the ceiling. But if you cover them up, how do you get to them?



With top and bottom covers removed, the 751 struts its stuff; it's not for the timid.

MULTI-BAND SLOPERS

160, 80, and 40 meters

Outstanding DX performance of slopers is well known. Now you can enjoy 2 or 3 band BIG-SIGNAL reports! Automatic bandswitching • Very low SWR • Coax feed • 2kw power • Compact • Ground or tower feed • Hang from any support 25 ft. high or higher • Easy to install • Very low profile • Complete instructions • Immediate shipment • Check ok

3 BAND SLOPER · 160, 80, & 40 Meters · 60 ft. long	$ 43.00 frt.ppd
2 BAND SLOPER · 80 & 40 Meters · 41 ft. long	$ 30.00 frt.ppd.
3-BAND NO TRAP DIPOLE, 160, 80, & 40M · 113 ft. long	$ 66.00 frt.ppd.
2-BAND NO TRAP DIPOLE, 80, & 40M · 84 ft. long	$ 49.00 frt.ppd.

tough to hear the beat note. Second, owing to the shape of the CALIBRATOR knob, it was difficult for me to make fine adjustments. I did find that by watching the S-meter fluctuations, I could zero-beat "visually" better than audibly. The little nub-like switches for the preamp and MARKER switches make it difficult to distinguish their positions, too.

Along with the preamp and calibrate controls are the MONITOR and ANTI-VOX controls, both of which are the same difficult-to-grasp shape. Luckily, these are not used often. And, in all fairness, considering the rock-solid stability of the 751, the calibrate controls won't get used much either. From early morning turn-on until late-night power off, I could detect only a very minute audible (or visual) calibration drift from WWV.

The transmitter, too, is completely solid-state with a "dial-your-power" control. It is protected from over-temperature by a two-speed, on-demand fan cooling system: Until the temperature of the final's heat-sink structure reaches about 50° C, the fan is off. When 50° C is reached, the fan comes on and stays on in both receive and transmit. Should the temperature climb to 90° C, the fan kicks into high and output power is reduced to 50 Watts. According to Icom, the temperature should never get this high unless there's a problem such as a mismatch or, perhaps, restricted air flow (contests and DXpeditions notwithstanding).

Icom also warns against operating into a vswr greater than 2 to 1, apparently because the protection circuitry can't cope. Reduced power and antenna tuners are also suggested for problem matches. Using the 751's built-in swr meter, I managed to load up easily on 80 through 10.

Although there isn't room in this review to explain adequately all the possible memory/vfo(s)/scan permutations, it quickly became obvious that from a frequency-handling perspective, the 751 should be great for contests and DX. There are two

vfo's, a DUPLEX switch to set them up for splits, and both receive and transmit offset provisions. Vfo's can be equalized, that is, set to each other instantly by pressing A = B, and memory frequencies and modes can be dumped into the vfo's by touching another switch.

The 751 offers a very flexible scan mode along with squelch control. Basically, you can set it to scan (top to bottom) (1) the entire general-coverage band, (2) within the limits of the frequencies set in memory positions 01 and 02, (3) all the memory channels, and (4) all the memory channels with a certain mode (such as AM) that you specify. Depending on SQUELCH control setting, the 751 will pause for about 10 seconds on every active frequency before continuing on.

All in all, I would recommend that you get hold of a 751 and do a personal evaluation. You'll need some time, though, to really explore its capabilities. And if all the options promised by Icom materialize, bring a lunch. Versatility is the watchword, and Icom has it.

For further information, contact *Icom America, Inc., 2112-116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

LETTERS

BIG GUN, BIG MOUTH

I read your magazine almost monthly and enjoy thoroughly some of the columns, especially the DX column by Chod Harris VP2ML.

The Heard Island story of August, 1983, was enlightening and my hat is off to the crew that brought that DXpedition to fruition. What courage, stamina, and financial burden that crew endured.

I was, however, upset at the boxed story accompanying the column, "Pileup Busting—By the Experts." What the experts had to say was helpful and based on knowledgeable operating and courteous common sense—except for the comments by K8CW. I find his comments very elitist. He eliminates transceiver-equipped stations by using wide splits. I would guess that he eliminates many average hams also. He also gives the edge to the big-signal stations—antenna farms and probably big amplifiers.

Based on K8CW's elitist attitude, I don't have much of a chance to ever work the big-time DXpeditions because, at present, all I have is a transceiver and a small 3-element beam—hardly an antenna farm.

Additionally, the time K8CW spends maintaining his blacklist could be better spent making quality contacts. I find his blacklisting 180 degrees out of phase with the tenets of amateur radio. Yes, I do agree that there are some inconsiderate operators out there when it comes to DX, but wouldn't it better to educate these people to the proper way of operating so that everyone gains?

Dick Jacovino KA1YP
Waterbury CT

HAM HELP WORKS!

My request in "Ham Help" for a manual on the Knight G-30 grid-dip meter has resulted in manuals, cards, and letters. How do I get them to stop?! The response has been outstanding, indicating the mutual concern of the ham family. I would like to suggest in such instances that a card or note precede the copying and mailing of requested material. I have felt obligated to reimburse those who sent the manuals and now have an adequate supply—plus!

James E. Smith K5PTC
Irving TX

PETER, PAUL, AND STUART

Several months ago you published a rather savage editorial criticizing the September/October, 1982, Peter and Paul expedition. I was a bit surprised, since none of the five operators had been checked for their side of the story of why the wide bandspread on 20 meters.

As the team leader, I must take full responsibility for what happened, despite the fact that I did not operate 20-meter phone when it became apparent that the situation was completely out of control. I can assure you that on my next DXpedition, I will utilize selective calling and keep the bandspread down to an extremely reasonable width.

I suspect you are not aware of the following facts:

- During the five days spent on the island, only two meals were provided by the Captain.
- Despite the equatorial location of the rocks, it was cold at night and there was insufficient foul-weather gear. The five of us crewed the vessel for five days and were exhausted when we arrived.
- The Captain refused to permit us to bring a table, so we made do with three pieces of plywood supported by loose basalt rocks for the stations. IDXF loaned us a 901 DM (which served on Spratly, 9M6, CR9, VS5, Desecheo, Navassa) and also a 101ZD which was used on Desecheo and Navassa. Both transceivers were disabled within the first four hours of operation. The band-selector shaft on the 901 snapped and one board failed. Carrier output was available but no audio and no receive could be obtained. The 101ZD received but no rf output could be obtained. Accordingly, for CW, K8CW and PY2CPU utilized a 101E belonging to K8CW and PY2BZD. N4BQW and I used a very old 101ZP with a bad front end belonging to PY2BZD.
- I had no problem working SSB and 10, 15, and 40. However, please bear in mind that the location of the rock is equidistant between Europe and the States, and despite the fact that the 101ZD had full rf attenuation, most signals were 30 over 9—no receiver can handle several hundred stations calling at the same time in a 20-kHz split. I am sure you are aware that 20-meter phone operators increasingly are using monobanders and full legal (?) limit amplifiers; many of them are using equipment without receivers. In other words, many did not listen. This created a problem for the policemen who were fighting with each other at 14.195. As soon as the operator concerned became aware of the problem and told me, I took the phone station off of 20 and put it on 40 where there was no trouble
- A recent Pacific Island trip to a quasi-rare spot produced the same incredible band split on 10-meter phone without complaint or editorials.

K8CW need not apologize for his performance. He made 6,000 contacts as PY9ZSC and 24,000 of the total 29,000 contacts from Heard Island. I did a respectable job on Desecheo and produced 6,000 contacts on Navassa in four days. Bearing in mind the adverse conditions, hunger, illness of three operators, tides which forced us to move the stations at night, sharks between the rocks, and a medical emergency which caused N4BQW to leave the island to attend an injured Brazilian sailor on a visiting boat for a period of eight hours, frankly, I am surprised that we produced 16,000 contacts in four days. I am also surprised that, despite our repeated requests for no duplicate contacts, station after station "duped" us, including many prominent DXers.

You are free to print this letter, and I would be interested in receiving your own thoughts. I plan to operate from another needed location in the next few months and from a very badly needed country as soon as licensing formalities can be completed. I can assure you that if there is another problem on 20 meters while I am operating, I will QSY to CW or drop the operation to 40 or 80 meters.

Stuart P. Greene WA2MOE
Peekskill NY

DISTORTED REASONING

I wish to comment on the dropping of the required facility in Morse code from amateur-radio licensing requirements.

I have been a ham since April, 1982, and hold a Canadian amateur-class license. I am restricted mainly to A1 operation on the HF bands but do enjoy limited phone privileges on 10 meters. I am also allowed phone privileges on various frequences in the VHF and UHF portions of the radio-frequency spectrum.

I am concerned about the current effort, both within and without the American amateur community, to integrate a codeless amateur license within the parameters of the American licensing program.

I do not believe a codeless license will attract a substantial number of newcomers to amateur radio. Further, there seems to be a belief that theory requirements should be made more demanding in order to attract technically-inclined individuals to amateur radio.

This kind of distorted reasoning is very unhealthy for amateur radio. In studying for my licenses, the learning of radio theory presented a greater hurdle to me in obtaining an amateur license than did the required facility in Morse code.

I enrolled in a ham-club-sanctioned licensing course, attended every lecture, and diligently studied all of the assigned readings. Of 45 individuals who began the course, only 6 students were successful in obtaining their licenses—a dismal 12% success rate. Had it not been for the kind help of a very good friend, I too would have failed in my quest for that coveted "ticket."

Judging from the comments of many, hams and non-hams alike, this is not a singular experience. It illustrates clearly that problems exist in the manner in which electronics is currently published and taught.

Currently, theory is presented in an often complicated, confused, and dry manner. Efforts must be made to ensure that the theory upon which our hobby is based is available to individuals in a simpler and more attractive mode. At the same time, efforts must be made to make the learning of code less of an obstacle to potential radio amateurs.

Because code is the simplest means of radio communication, it is, by its nature, something with which all amateurs have some familiarity. Consequently, it is not unreasonable to expect prospective amateurs to display competence in its transmission.

A common thread binds all amateurs together, that being the camaraderie and fellowship which is the essence of our hobby. The theory changes proposed by eager technophiles can only hurt amateur radio, due to the basic elitism inherent in any such proposals—elitism totally foreign to the essential spirit of hamming.

We amateurs must increase involvement by the community in amateur radio. To do otherwise will ensure our hobby will continue to be trivialized in the public mind. Thus, growth in the ranks of amateur radio will be very limited.

Arthur Cramer VE4ACM
Winnipeg MAN

Well, Arthur, I'm not sure where you are reading these things—certainly not in my editorials. While I am not a fan of the Morse code, feeling that it should have been eliminated as a requirement for a license at least 50 years ago and promoted as a fun means of communication in order to retain popularity, I don't recall ever claiming that dropping the code would bring in more hams. On the contrary, I doubt if this would make a lot of difference. If we want hams, we'd better start letting teenagers know about our hobby and promoting ham clubs in high schools like we used to when the hobby was growing.

I think we should have a legitimate technical, rule, and operations exam. The material doesn't have to be any more difficult than presently required. We should have the exams given by clubs so we can get away from the memorization/Bash syndrome. You sure are right about there being a need for a better book explaining the theory, though our study manual is pretty darned good in this line. Perhaps there is someone out there who would like to write a real fun introduction to electronic and radio theory.—Wayne.

CASH OR CREDIT

One of the amateur-radio-magazine editors has been decrying the lack of interest by young students in science studies. He claims that other nations' youth are passing ours by. There is credence in his utterances.

I am aware of one individual who has arisen to inform our youth about at least one facet of science. At Junior High School No. 22 in the heart of New York City, Joseph J. Fairclough WB2JKJ has been teaching his youngsters a course in "Ham Radio English."

Joe has wall-to-wall QSL cards decorating his classroom. His students happily talk over his station situated near his desk. I

have visited the school and I have talked to the students in his classroom via amateur radio. I know that Joe has given those kids a good course in English and successfully planted the seeds of amateur radio into their fertile minds.

During my high school days I was fired with enthusiasm for ham radio by membership in the school's radio club under the trusteeship of the school's physics department. That enthusiasm never died. It had a profound effect upon my career.

Recently, as a guest of the Martinsville, Indiana, Radio Club, I proposed the installing and maintaining of high school and junior high school radio clubs in the schools of our land wherever practicable, to be trusteed by a faculty member friendly to ham radio and to be sponsored by local QCWA, SOWP, ARRL, and other amateur-radio organizations. Sponsorship would include guidance, assistance in setting up a station, and follow-up to see that the station is properly operated (not devastated in the manner of many club stations). Of course, the local sponsoring club would have to be a viable, responsive group as well.

I feel that such a program would be more effective than the cash donations now given to gifted youth.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

FARIBAULT MN
DEC 3

The annual Handi-Ham Winter Hamfest will be held on Saturday, December 3, 1983, at the Eagles Club in Faribault MN. Registration will begin at 9:00 am. There will be a Handi-Ham equipment auction and a dinner at noon. Talk-in on .19/.79. For more information, contact Don Franz W0FIT, 1114 Frank Avenue, Albert Lea MN 56007.

HAZEL PARK MI
DEC 4

The 18th annual Hazel Park Amateur Radio Club Swap and Shop will be held on Sunday, December 4, 1983, from 8:00 am to 2:00 pm, at Hazel Park High School, Hazel Park MI. Tickets are $1.50 in advance and $2.00 at the door. Tables are $1.00 per foot. Hot food and plenty of free parking will be available. Talk-in on .52 simplex. For tickets and table reservations, write HPARC, PO Box 368, Hazel Park MI 48030, or phone (313)-544-2965.

WEST ALLIS WI
JAN 7

The West Allis Radio Amateur Club will hold its 12th annual Midwinter Swapfest on Saturday, January 7, 1984, beginning at 8:00 am, at the Waukesha County Expo Center Forum (take I-94 to Co. F, then south to FT, then west to Expo). Admission is $2.00 in advance and $3.00 at the door. Tables are $3.00 in advance (reserved until 11:00 am) and $4.00 at the door on a first-come, first-served basis. Delicious food will be available. For tickets or more information, send SASE to WARAC, PO Box 1072, Milwaukee WI 53201.

SOUTH BEND IN
JAN 8

A hamfest swap & shop will be held on Sunday, January 8, 1984, at Century Center, downtown on US 33 Oneway North between the St. Joseph Bank Building and the river, South Bend IN. Tables are $3.00 each in a carpeted half-acre room. The Industrial History Museum is in the same building. Four-lane highways lead to the door from all directions. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, 145.43, and 145.29. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 48616, or phone (219)-233-5307.

YONKERS NY
JAN 22

The Yonkers Amateur Radio Club will sponsor the Yonkers Electronics Auction on Sunday, January 22, 1984, from 9:00 am to 3:00 pm, at Lempko Hall, 556 Yonkers Avenue, Yonkers NY. Admission for buyers and sellers is $3.00 each; children under 8 will be admitted free. New and used equipment will be auctioned and can be inspected from 9:00 am to 10:00 am. There will be plenty of seats and parking and the auction will start at 10:00 am sharp. Unlimited free coffee will be available all day. The club will charge a 10% commission on the first $100 and 5% on the remainder on successful sales only. Talk-in on 146.265T/146.865R and .52 direct. For more information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

MANSFIELD OH
FEB 12

The Mansfield Midwinter Hamfest/Auction will be held on Sunday, February 12, 1984, beginning at 8:00 am, at the Richland County Fairgrounds, Mansfield OH. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Half tables are available. Talk-in on 146.34/.94. For additional information or advance tickets and tables, send an SASE to Dean Wrasse KB8MG, 1094 Beal Road, Mansfield OH 44905, or phone (419)-589-2415.

GLASGOW KY
FEB 25

The annual Glasgow Swapfest will be held on Saturday, February 25, 1984, beginning at 8:00 am Central time, at the Glasgow Flea Market Building, 2 miles south of Glasgow, just off highway 31E. Admission is $2.00 per person. There is no additional charge for exhibitors. The first table per exhibitor will be free, and extra tables will be available for $3.00 each. There will be a large heated building, free parking, free coffee, and a large flea market. Talk-in on 146.34/.94 or 147.63/.03. For further information, write Bernie Schwitzgebel WA4JZO, 121 Adairland Court, Glasgow KY 42141.

SIGNAL GENERATORS
RECONDITIONED AND LAB CALIBRATED

AN/URM-25 MILITARY SIG GEN, RANGE 10 KHZ THRU 50 MHZ, AM/CW, MODULATION 400/1000 HZ, CALIBRATED OUTPUT PRECISION 50 OHM STOP ATTENUATOR $285.00

AN/URM-26 MILITARY SIG GEN RANGE 4 MHZ THRU 405 MHZ, 400/1000 HZ MODULATION, CALIBRATED OUTPUT, SMALL COMPACT SIZE $285.00

TS-510/U MILITARY SIG GEN, RANGE 10 MHZ THRU 420 MHZ, OUTPUT VOLTAGE .5V TO 1V, MODULATION 400/1000 HZ AM/CW OR PULSE, SAME AS HP-608D $345.00

HP-614 SIG GEN, RANGE 900 MHZ THRU 2100 MHZ, AM/PULSE MODULATION CALIBRATED OUTPUT, IDEAL FOR AMATEUR 1.2 GHZ, MICROWAVE OR AIRCRAFT RADIO REPAIR $345.00

SG-557/URM-52 MILITARY SIG GEN, RANGE 3.8 GHZ THRU 7.8 GHZ, AM/PULSE CALIBRATED ATTENUATOR, MILITARY EQUIVALENT TO HP-618A, IDEAL FOR SATELLITE OR MICROWAVE REPAIR $345.00

TS-418/URM-49 RANGE 400 MHZ THRU 1000 MHZ, AM/CW OR PULSE MODULATION, CALIBRATED ATTENUATOR $225.00

TS-419/URM-64 RANGE 900 THRU 2100 MHZ, CW OR PULSE MODULATION, CALIBRATED ATTENUATOR $225.00

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½"×11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I desperately need a circuit for an automatic line-voltage compensator for my 120-V, 12-A recreational-vehicle air conditioner.

Zoltan R. Bogar W3CJM
1921 Marymont Road
Silver Spring MD 20906

My husband, William Peuser W2BBS, passed away recently and I don't know what to do with his equipment. He had a Collins 75A receiver, Heath SB-220 linear, Heath SB-401 transmitter, Vibroplex key, Triplet frequency meter, Heath VTVM, and set of headphones. If anyone would like to buy this equipment, please let me know.

Veronica Pause
12-42 120th St
College Point NY 1135

I would appreciate information on adding FM capability to my Yaesu FT-301D. I would also like to find a service manual for it.

Dave Mastenbrook KA7BK
38682 Golden Valley Driv
Lebanon OR 9735

I would like to borrow a Heath IO-10 oscilloscope. I will pay the postage both ways and return it in two weeks.

Frank Aldrich N0AF

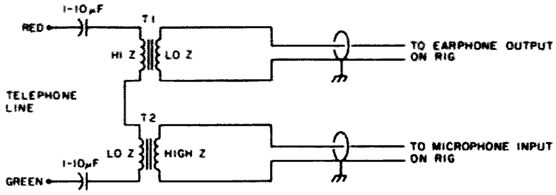
Boulder CO 803C

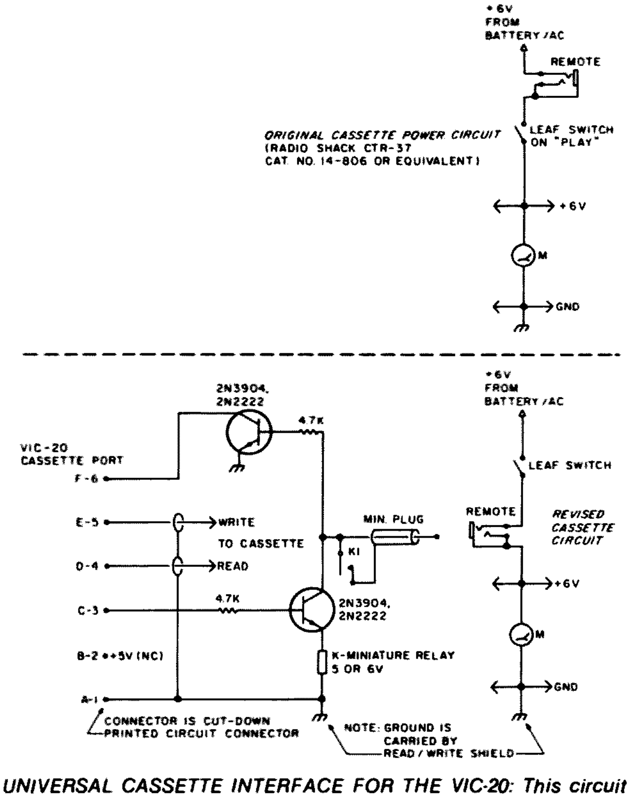
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

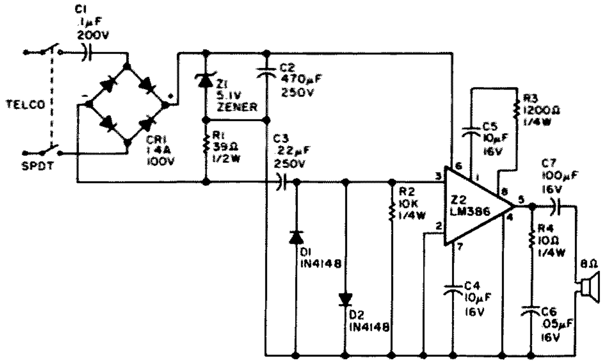
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



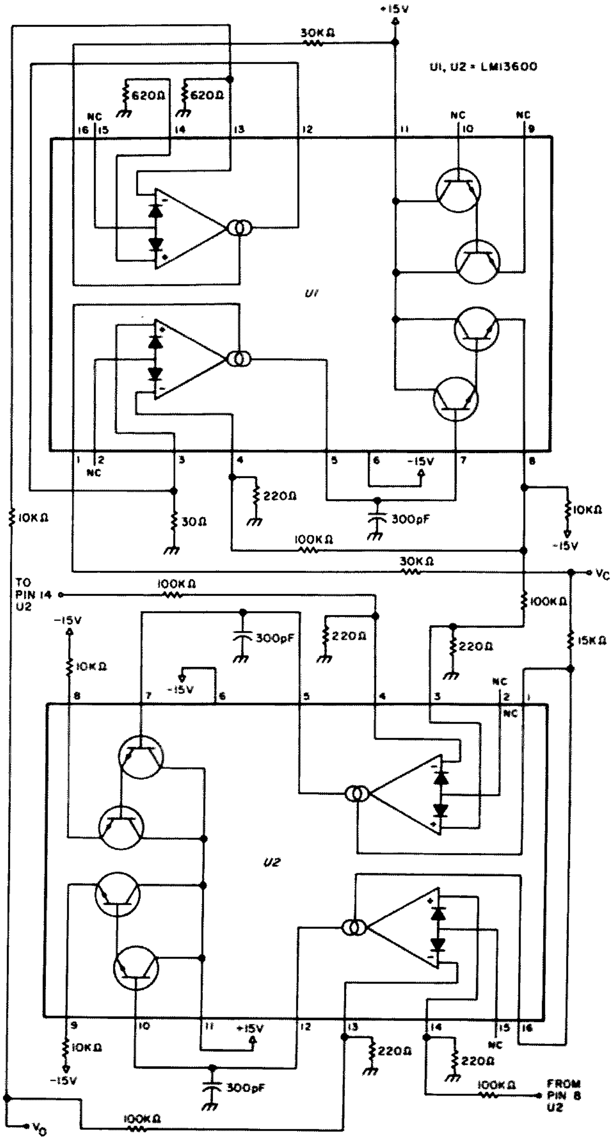
NO-COST PHONE PATCH: By scrounging two transformers from transistorized broadcast-band radios, you can make this phone patch for your HF rig. The low- and high-impedance windings were determined by using a VOM to measure the resistance; the transformers I used had about a 30:1 resistance ratio. It is possible to use VOX with this circuit if the anti-VOX is adjusted properly and the phone lines are not noisy.—Terry Fletcher WA0ITP, Ottumwa IA.



UNIVERSAL CASSETTE INTERFACE FOR THE VIC-20: This circuit will allow you to use any cassette recorder with the VIC-20, but does not prohibit normal use. To use the circuit, the recorder must be rewired so that power from the battery will go first to the leaf switch and then to the remote jack. The circuit is not critical and in operation, the normal "save," "verify," "search," and "load" commands apply.—George W. Allen N1BEP, Old Greenwich CT.



TELEPHONE LINE MONITOR: Using rectified audio as a power supply, this monitor will put the telephone-line audio into an 8-Ohm speaker. All of the parts are available from Radio Shack.—E. C. Sherrill W5TPP, Fort Worth TX.



SINUSOIDAL VCO: Using two National Semiconductor LM 13600N dual transconductance amplifier chips, this circuit provides a variable frequency output dependent on the input voltage. The circuit's frequency range is from 5 Hz to 50 kHz with a total harmonic distortion of less than 1 percent.—Paul F. Cavanaugh N2DLV/G5EHU.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

WASHINGTON TOTEM AWARD

The Washington Totem Award was initiated in 1973 by the Western Washington DX Club, thus becoming the first major W7 award available to the amateur community. It used as its motif the colorful totem pole, symbolic of the Indian culture of the Pacific Northwest.

The first award was issued to 9X5NA; to date, 133 awards have been issued to 61 DX countries. To qualify:

Applicants must submit proof of QSOs with 100 different Washington stations. Twenty (20) of these must be confirmed contacts with different Western Washington DX Club members. DX stations need only confirm twenty-five (25) Washington stations including ten (10) WWDXC members.

General certification rules apply. Submission of QSL cards is not required. Cards may be checked and certified by an officer of any recognized club or society. DX stations may submit log data in lieu of QSL card confirmation.

To be valid, all contacts must have been made January 1, 1973, or later.

Certified lists submitted must be in alphabetical order, with date and time in GMT.

The Washington Totem Award is free to all stations outside the United States. US stations must include an application fee of $1.00. If QSL cards are sent to WWDXC for checking, sufficient postage for their safe return must be included with the application and confirmation list.

Special endorsements will be issued for specific band or mode accomplishments if all supporting information is included with the application.

The WWDXC will furnish a current membership listing upon request (and SASE). Mail all inquiries to: Awards Manager, WWDXC, Inc., PO Box 224, Mercer Island WA 98040, USA.

I might hint to our readers wishing to seek this award that members of the Western Washington DX Club sponsor three DX nets daily. To be part of the "W7PHO Family Hour," tune to 14.225 MHz at 1400 and 2300 GMT and to 21.320 MHz at 0000 GMT daily.

BOEING AWARDS PROGRAM

The BEARS offer quite an array of incentives for parchment pursuers. Let's take a closer look at each one individually:

Worked Five Bears Award

This award is offered for those stations confirming contact with at least five (5) members of the Boeing Employees' Amateur Radio Society. There are no band, mode, or time restrictions. General certification rules apply.

Worked Three Bear Cubs Award

Issued specifically to any station confirming contact with at least three (3) Novice members of the Boeing Employees' Amateur Radio Society. There are no band, mode, or time restrictions. General certification rules apply.

Zone 3 Award

This award is offerd in four (4) levels of operating achievement:

Basic Zone 3 Award. This award is issued to those stations submitting written evidence of having worked an amateur in each state and Canadian province in Zone 3. These geographical limits would include Arizona, Oregon, California, Nevada, Utah, Washington, and the province of British Columbia. Contacts may be made in any amateur band and mode and must have been made on or after January 1, 1984.

Master Zone 3 Award. Applicant must follow the same rules as stated for the Basic Award with the exception that all contacts must be made with a station located in the capital city of each state and province in Zone 3.

Special Zone 3 Award. This special award recognition requires the applicant to work five (5) Zone 3 stations whose last call letters spell the word BEARS. All other rules for the Basic Zone 3 Award apply.

Extra Zone 3 Award. This award combines the difficulty of both the Master and Special awards and undoubtedly becomes the most sought-after in the Zone 3 program. To qualify, contacts must be made with stations located in capital cities of Zone 3 state and provinces. In addition, the last letters of their calls must spell the word BEARS.

All awards offered by the BEARS are available free of charge. Applicants must make a self-prepared list of required contacts, including the city and state of each amateur contact claimed, the date of each QSO, the band, and the mode. This list must be verified by at least two (2) amateurs, Technicians or above, an officer of an active radio club, or a notary public. In each case, the applicant must have written confirmations on hand for each contact claimed. Submit your award application to: The Boeing Employees' Amateur Radio Society, Willis Propst K7RS, 18415 38th Avenue, South Seattle WA 98188.

SRAL AWARDS

The Finnish Amateur Radio League award manager writes to inform us about the beautiful OH series of awards being offered by this dedicated organization in northern Europe.

All applications must be forwarded to the attention of the SRAL Award Manager, PO Box 306, Helsinki 10, Finland; it is suggested that QSL cards not be sent. Instead, claimed contacts should be verified locally by two licensed amateurs, a club official or a notary public.

To be valid, all contacts qualifying for the OH-series awards must have been made since June 10, 1947. The OH awards consist of the following:

OHA

Applicants in Denmark, Norway, and Sweden need contacts with at least 50 different OH stations, including 8 OH call areas on one band, plus 8 different OH call areas together on other band(s).

Other European applicants need contacts with at least 20 different OH stations, including at least 7 OH call areas. The maximum number of contacts per band is 15, so at least two different bands must be used.

Non-European applicants need contacts with 15 different OH stations, including at least 5 OH call areas on any band or combination of bands. Contacts made on 3.5 MHz will count for two contact points.

CW, phone, or mixed-mode contacts count. The minimum acceptable reports are 338 RS(T). Contacts with Finnish maritime mobile stations do not count.

The award fee is 5 IRCs, to be sent with each application.

The OH8 stations with suffixes ND, NJ, NS, NV, NX, OA, OB, OC, OG, OI, ON, OP, OO, OR, OU, OX, OZ, PA, PB, PD, PF, PL, PM, and PO are counted as OH9 stations if the contacts occurred before June 1, 1954.

OHA-100

The applicant must have worked at least 100 different OH stations, including all 10 call areas on one band plus (again) all 10 OH call areas on another (one) band. The 100 stations must all be different, but in order to meet the call-area requirement, the same station may be worked on different bands; in this case, the total number of contacts will be over 100. All authorized bands may be used, as well as CW, phone, or both.

The application list must be in district and alphabetical order (only callsigns and dates), giving separate declaration of the required 2 × 10 call areas/bands.

See also paragraphs 4, 5, and 8 of OHA rules above.

OHA-300

The applicant must have worked and confirmed at least 300 different OH stations, including all 10 OH call areas separately on each of three bands, i.e., 3 × 10 OH districts. The 300 OH stations must be all different, but in order to meet the call-area/band requirement, the same OH station may be worked on different bands. In this case, the number of OSOs will exceed 300. All bands, CW, and/or phone may be used.

This application list must be in district and alphabetical order (only callsigns and dates), giving separate declaration of the required 3 × 10 districts/bands.

OHA-500

This award will be available to any foreign applicant for confirmed contact with 500 different OH stations, regardless of time, mode, or band used. For OH applicants, only contacts made since February 1, 1967, will count.

A list of the 500 OH QSL cards on hand must be submitted to the awards manager. As with all OH-series awards, this list must be verified by at least two amateurs, a club official, or a notary public. The award manager reserves the right to call for any QSL to be submitted in support of any claim. This list must be written in alphabetical order by callsign, and no other details are necessary.

The OHA-500 is given to qualified applicants free of charge, compliments of SRAL.

WIA AWARDS

From down under, the boys at the Wireless Institute of Australia were kind enough to present the entire portfolio of WIA-sponsored achievement awards. We will review the well-known Worked All VK Call Areas Award.

This award is offered by the WIA as tangible evidence of the proficiency of overseas amateurs in making contacts with the various call areas of the Commonwealth of Australia.

The award may be claimed by any amateur in the world who is a member of an affiliated society of the IARU, but no Austra-

VK TERRITORIES

Territory	Call Area	QSLs Required
Australian Antarctica Heard Island Macquarie Island	VK0	1
Australian Capital	VK1	1
Lord Howe Island State of New South Wales	VK2	3
State of Victoria	VK3	3
State of Queensland Thursday Island Willis Island	VK4	3
State of South Australia	VK5	3
State of Western Australia	VK6	3
Flinders Island King Island State of Tasmania	VK7	3
Northern Territory	VK8	1
Admiralty Islands Bougainville Island Christmas Island Cocos Islands Nauru New Guinea New Ireland Norfolk Island Papua Territory	VK9	1

Table 1. In areas above where more than one confirmation is required, contacts may be made with any or all of the territories grouped together. VK9: Where a territory is no longer under Australian jurisdiction, contacts up to the date of independence will be accepted.

lian amateur will be eligible.

A handsome certificate will be awarded to any applicant who makes contacts with Australian amateur stations in the areas shown in Table 1. A total of 22 contacts must be made.

Contacts between overeas stations and Australian stations must have been made on or after January 1, 1946.

Contacts may be made using any authorized frequency band or type of emission permitted to Australian amateurs, but crossband contacts will not be allowed.

No contacts made with ship or aircraft stations in Australian territories will be eligible, but land-mobile or portable stations may be contacted provided the location at the time of contact is shown on the confirmation.

The applicant must submit proof in the form of QSL cards or another form or written evidence confirming two-way contacts have been made. Such verification must show the date and time of contact, call of the station worked, type of emission and frequency used, signal reports, and location (portable or land mobile stations only) of the stations contacted.

If the applicant is a member of a society which has a reciprocal agreement with WIA to verify claimed contacts for its members, submit your QSLs to that society, being sure to enclose sufficient postage fees for their safe return.

Applicants should submit their certified list of contacts and/or list of contacts with QSL cards to: the Federal Awards Manager, WIA, Postbox 150, Toorak, Victoria 3142, Australia. There is no fee for the award—it's compliments of WIA.

MARK TWAIN SPECIAL-EVENT STATION

The Connecticut DX Association will operate special-event station KO1R from 1300Z to 2000Z on Saturday, December 3, 1983, from the home of Mark Twain, The Mark Twain Memorial, in Hartford, Connecticut. The frequencies for both phone and CW will be the lower portion of the General and the upper portion of the Advanced bands. For a full-color QSL, send your QSL and SASE to: Connecticut DX Association, PO Box 181, Columbia CT 06237.

EVERGLADES ARC NATIONAL PARK SPECIAL-EVENT STATION

The Homestead, Florida, Everglades Amateur Radio Club will be operating special-event station W4SVI from 1300 UTC December 3 to 2200 December 4, 1983, in celebration of the 36th anniversary of Everglades National Park.

Operations will be 10 kHz up from the lower edge of the 40–10-meter General phone bands and Novice bands. W4SVI will also be on 146.52 MHz. A special certificate is available for a QSL and large SASE. Mail it to: W4SVI, c/o Dick Dowst WB4HZK, Everglades ARC, 14511 SW 287 St., Leisure City FL 33033.

HEN HOUSE GANG CHRISTMAS SPECIAL

W1FHP and the Hen House Gang of Bethlehem, Connecticut, will have its annual Christmas special from November 26, 1983, to January 7, 1984. They will be spreading Christmas cheer to children of all ages by relaying messages to Saint Nick. Operating frequencies will be on all bands from 40 to 10 meters. QSLs should be sent to the *Callbook* address with a 20-cent stamp.

NEW PRODUCTS

DC INSERTER FOR BLOCK DOWNCONVERTERS

The model 4408-FM/FF is used to block or insert dc power into a TVRO system downconverter. Operating frequency range is 220 MHz to 720 MHz.

When placed between the receiver and downconverter, dc power can be sent through the center coax conductor. Model #4408 comes with type F connectors, one male and one female, and you can specify a male or female input connector. Impedance is 75 Ohms, and the maximum insertion loss is 0.5 dB. Minimum insertion loss is 14 dB.

For more information, contact *Microwave Filter Co., Inc., 6743 Kinne Street, East Syracuse NY 13057; (800)-448-1666.* Reader Service number 480.

The 4408-FM/FF dc inserter from Microwave Filter Co.

PACKET-RADIO TERMINAL NODE CONTROLLER

GLB Electronics has announced the Model PK1 low-cost TNC for packet radio. This unit has a self-contained modem and requires a 12-volt power supply, a data terminal, and a radio transceiver for packet operation. The data terminal can be a personal computer, a "dumb" terminal (keyboard and display), or even a mechanical teletype machine. The terminal interface is RS-232 compatible and self-adapts to ASCII or Baudot at data rates ranging from 45 to 9600 baud. An adapter is available for converting mechanical teletype machines to the RS-232 interface.

On the radio-link side, standard Bell 202 tones are used, with a data rate of 1200 baud, making it compatible with Vancouver and Tuscon TNCs.

Utilizing a Z80A microprocessor, the Model PK1 has 8K of ROM and 4K of RAM as standard equipment. RAM can be readily expanded to 14K, using 2K "byte-wide" memory chips, and to 56K via modification using 8K chips. The VADCG protocol is available now, and AX.25 is to be released by the end of the year. Conversion to AX.25 is accomplished by means of exchanging ROMs at nominal cost.

The unit is ready to operate on power-up with a few simple commands, but there are over 50 total commands available for control and to set operating modes and parameters. Included are ways to operate in connected and unconnected modes and even to create custom protocols via a host computer. A CW identifier is also included.

In the "Queue-up" mode, messages or data are automatically stored in internal memory. They can then be taken one at a time or all at once at the operator's convenience. A "Block" mode is available for interfacing to a host computer, where all data is transferred via a counter, permitting unrestricted flow of data having arbitrary byte values and sequences. Numeric values can be set to decimal, hex, octal, or binary with or without leading zeros. Console echo is optional, as is automatic line feed, a terminal width limit, and automatic null insertion.

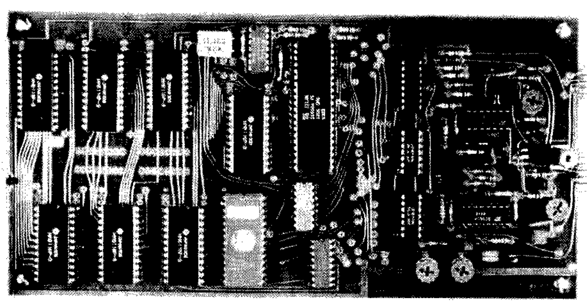
Besides information, display output optionally includes non-info data, packet headers, error indications, and current link status. Each of these fields can be independently disabled or enabled. So the user may choose anything from "pure" data to all the workings of the packet environment. Each field is uniquely identifiable by machine, simplifying automatic operation controlled by a host computer.

Applications include conversations, message handling, file transfers, automatic bulletin boards, etc.

The PK1 can be used as a "private" message-handling system in conjunction with a teletype machine. When a message is available it activates the motor, prints the message(s), and shuts off automatically. A user can select all-channel activity, messages from a specific station, or only those messages intended for him to be displayed.

The Model PK1 is a printed-circuit assembly, measuring 4.5 × 9.4 inches, including two 10-pin edge connectors. Power required is a single +12-volt supply at 1/4 Ampere. Connecting cables are also available.

For more information, contact *GLB Electronics, 1952 Clinton St., Buffalo NY 14206; (716)-824-7936.* Reader Service number 477.



GLB Electronics' Model PK1 TNC.

HUSTLER 440-MHZ FIXED-STATION VERTICAL

The new G6-440 delivers 6 dB gain in an omnidirectional pattern with the major lobe at the horizon, making it ideal for repeater use. The stack of 5/8-wave vertical radiators is sealed in a white fiberglass radome for all-weather use. Mounting support is aluminum with stainless-steel hardware. No tuning is required, since resonance is factory adjusted to 440 MHz with a bandwidth of 18 MHz under 2:1 vswr.

For more information, contact your local dealer or write *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.* Reader Service number 486.

MAXCOM ANTENNA MATCHER

The Maxcom antenna matcher will tune a dipole or longwire antenna configuration, from .3 MHz to 70 MHz, with a vswr of less than 1.5 to 1.

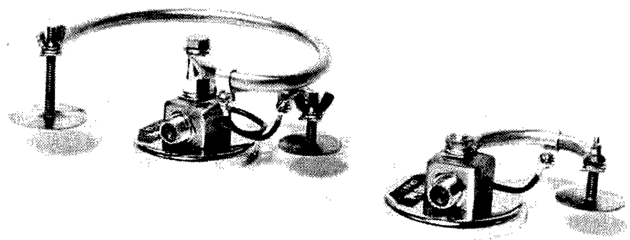
The small size and weight of the matcher makes Maxcom ideal for land, marine-base, and avionics applications. Originally developed for military applications, the broadband coverage provides the user with one antenna for operation on many frequencies, thus eliminating multi-antenna dipole and longwire installations which not only are unsightly but also, in most cases, interact due to space restric-

tions. Maxcom is small, lightweight, efficient, and almost invisible in comparison.

When used in a dipole configuration each leg of the dipole must be at least 35 feet long. Changes in angle and elevation will alter the directivity but will not affect Maxcom's ability to match the antenna. Inverted-V configurations have proven to be the preferred installation with Maxcom.

Longwires may also be used, provided that a substantial ground is connected to the correct terminal on the Maxcom. The Maxcom is particularly well suited for sloper configurations.

For additional information, contact *Magnum Distributing Inc., 1000 S. Dixie Highway W. #3, Pompano Beach FL 33060; (305)-785-2002.* Reader Service number 483.



Com-Rad Industries' CR2/4A and CR4A antennas.

MFJ-103 24/12-HOUR DIGITAL CLOCK

The MFJ-103 is a new 24/12-hour, solid-state, digital clock. It features blue, 0.6-inch vacuum fluorescent digits. This new clock has a battery backup to keep the clock on time during power outages. It requires a single 9-volt battery (not furnished).

It has an ID timer that alerts you every 9 minutes after you tap the ID/snooze button. This 9-minute timer gives you a full minute after the timer sounds to indentify and still be legal. It has a switchable seconds readout for accuracy. It can be synchronized with WWV.

The MFJ-103 has an alarm for schedule reminder or wake-up use. An alarm indicator tells you when the alarm is on.

For "observed-time" timing, just start the clock from zero and note the ending of the event up to 24 hours. It has fast and slow set buttons for easy setting and a lock function to prevent mis-setting.

The clock operates on 110 V ac, 60 Hz, and is UL approved. The handsome, black plastic case with clear front measures 5 × 2 × 3 inches.

MFJ provides a 30-day money-back trial period. If you are not satisfied, you may return it within 30 days for a full refund (less shipping). MFJ also provides a one-year limited warranty.

For additional information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 476.

The new MFJ-103 24/12-hour digital clock.

DAIWA LA2155 150-W 2M LINEAR AMPLIFIER

Daiwa has introduced a new, high-power two-meter linear amplifier—the LA2155. The LA2155 delivers a 150-Watt punch with 25 Watts of FM, SSB, or CW input. The unit features an array of extras such as a switchable receive preamp, a high/low power option, fast acting protection circuitry, rf-activated transmit/receive switching with time delay and manual override option, and relative power output metering.

The LA2155 requires 12 V dc at 24 Amps maximum. For more information contact: *MCM Communications, 858 East Congress Park Drive, Centerville OH 45459; (513)-434-0031.* Reader Service number 478.

HEADLIGHTS

Headlights is a new portable light source for the repairman, handyman, and hobbyist, now available from Fogg and Egan. It directs bright light where you look while leaving both hands free to work. They light when you put them on, and there are no switches, wires, or battery packs. Headlights is designed to be worn with or without glasses. Two bulbs, 6 inches apart, flood the work area and are more effective than a single bulb in eliminating shadows in confined areas.

Headlights is ideal for times when the power is out, close-tolerance work, working in confined areas, reading in dim light, or performing any task where you need both hands free.

For more information, contact *Fogg and Egan, 17 Verdin Drive, New City NY 10956: (914)-634-5870.* Reader Service number 482.

COM-RAD'S 440-MHZ DDRR

Com-Rad Industries has added a 440-MHz DDRR to round out its family of rugged, low profile, flutter-free antennas for VHF and UHF service. The 440 unit is only 1-1/2 inches high and is made entirely from stainless steel and chromed brass (as are the units for 144 MHz and 220 MHz). The 440-MHz (CR4A) or the 220-MHz (CR3A) can be combined with the 144-MHz (CR2A) to form a two-band automatic bandswitching antenna using just one feedline.

These combination antennas are very useful when using the new dual-band transceivers that are coming on the market. Also, because of the low profile, the antennas can be mounted on the roof of a vehicle for maximum efficiency and a more uniform radiation pattern than is possible from a trunk or bumper. Both the 440-MHz and the new combination units incorporate the new capacity-disk tuning system which gives them an even lower profile and greater durability.

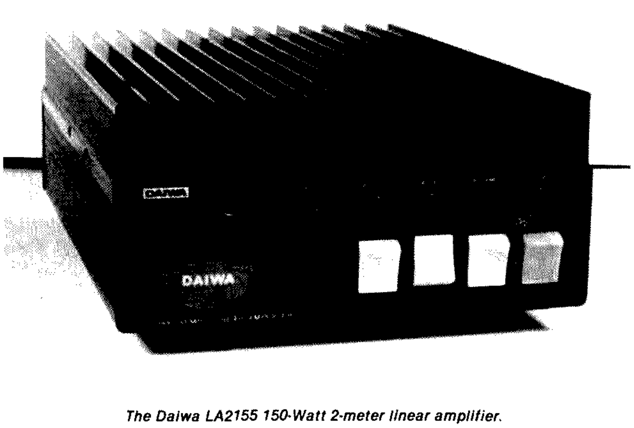
For additional information, contact *Com-Rad Industries, 1635 West River Parkway, Grand Island NY 14072; (716)-773-1445.* Reader Service number 484.

LARSEN TEST MOUNT ADAPTER

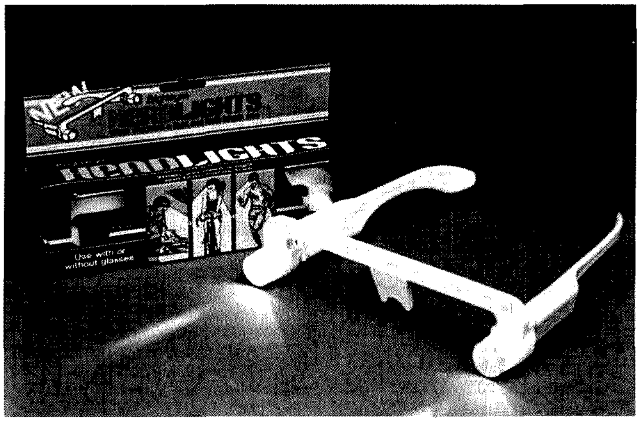
The new Larsen Electronics test mount adapter simplifies tracing problems in antenna or radio. It can check the antenna-feedline vswr and the radio power output at the same time. All you have to do is screw the adapter on the mount and apply a dummy load. Then check the coax, mount impedance, and connections.

The test mount has other uses as well. When you don't have clearance for a full antenna or just want to remote an antenna temporarily, you can use the adapter for a coax extension.

The test adapter is available for Larsen's NMO and NLA series mounts. For more information, contact *Larsen*



The Daiwa LA2155 150-Watt 2-meter linear amplifier.



Headlights portable light source from Fogg and Egan.

NEW MODS FOR KENWOOD TRANSCEIVERS

International Radio, Inc., formerly Users International Radio Club, has released several modification kits for Kenwood transceivers.

The TS-930S 2.1-kHz cascade kit features two 8-pole crystal filters, two diode-switching boards, all parts, and instructions. This kit does not require removal of the large signal-unit PC board. All soldering is done from the top of the PC board, and no insertion loss will be noted. The filter will increase your selectivity at 6 dB from 2.7 kHz to 2.0 kHz, and from 4.0 kHz to 2.5 kHz at 60 dB.

The TS-430S cascading kit will add another 8 poles of filtering for a total of 16 poles. The added filter is patched in before the product detector and is in the receive mode only. The kit will improve your noise-floor figures and front-end dynamic range and increase selectivity. The kit consists of a pre wired, tested PC board with a 2.1-kHz filter installed and complete instructions.

The Magicom speech processor will increase the average signal power to the antenna by as much as 6 dB. In addition, a significant "talk-power" improvement will be realized over existing processing methods used in the TS-430S. The processor comes wired, tested, and with complete instructions and pictorials.

For more information on these and other products, contact *International Radio, Inc., 364 Kilpatrick Avenue, Port St. Lucie FL 33452.* Reader Service number 481.

WHAT DO *YOU* THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Well, it's December—time for our annual shopping spree. Last year, I used the pages of *73* as an avenue of shops. Your response to this approach was so good that I think we will do it again. I would like to preface this with the note that, unlike those reviews I have written about equipment tested or evaluated here at WA3AJR, the material presented this month is basically what the manufacturer claims, without much in the way of screening. I shall provide the addresses of companies for you to contact directly, should you be interested in any of the items mentioned. Since they all are *73* advertisers, I am sure the magazine will stand alongside you as well.

That said, let's take a stroll down *73* Boulevard. We are only going to look at those advertisers who directly address the RTTY crowd, even though antennas, receivers, and the like may be important. With the proliferation of RTTY equipment being offered, I think it is important to spotlight that stuff! Also, we will be using the October, 1983, issue of *73* as a guide. So, if your favorite advertiser was not there, we may miss him.

How about a copy of the 1984 *Radio Amateur Callbook*? Selling for $19.95, this is an indispensable aid to any active amateur. The book contains, besides the expected listing of all amateur callsigns, call changes, silent keys, census data, QSL bureaus, and more. A buck less buys you the International edition with information on almost a half million amateurs worldwide. No ham should be without one!

The Ham Shack takes a page to announce AEA's CP-1 Computer Patch Interface. This little box patches many popular home computers to run both RTTY and CW. It appears to offer both fixed-170-Hz and variable shift, automatic threshold, and a built-in AFSK generator. Looks interesting—it might answer the need of quite a few hams looking to interface their small computer with amateur radio.

Our old buddies at Microlog, here in Maryland, have a two-page spread to announce their version of the home computer-RTTY interface. Their AIR-1 is a single-board terminal unit and operating system that converts a VIC-20 to run RTTY and CW. Now why they chose the VIC-20, with its 22-character line, is beyond me—it would seem as though this would limit one's communication of most forms of RTTY—but they did. I would rather have seen an Atari or the like; maybe they will come out with one for that system. But for this one, they have an impressive package, display notwithstanding. Text buffer, autostart, WRU (who are you?) mode, diddle, and even a real-time clock are some of the features. This package, retailing for $199, is something to be dealt with.

Software is in abundance, and the W. H. Nall Company is advertising a disk for the Apple II with a program named Egbert II. This program allows RTTY, CW, or TDD (deaf TTY on telephone) with a software terminal unit. At $59.95, $39.95 if RTTY only is desired, this sounds like quite a bargain. Would be interested to hear from any readers who have used the program.

Macrotronics, a company that entered the computer-RTTY market rather early, offers their Terminall, a hardware and software system which sends and receives RTTY and CW on a TRS-80 Model I or III (4?), Apple II (IIe?), or Atari 400/800 (1200/1400/1450?). The box sells for $499 and is all you need other than a transmitter and a receiver to put these computers on the air.

Another old friend, MFJ Enterprises, Inc., offers their RTTY/ASCII/CW Computer Interface. Using available software, this is a demodulator and AFSK generator that will act as the hardware interface between your radio equipment and, in their words, a VIC-20, TRS-80C, Atari, TI-99, Commodore 64, or almost any other personal computer. Remember now, this does *not* include the software to turn your computer into a terminal, just the decoding of the audio from your receiver into tones and the encoding of your RTTY pulses into a form that your transmitter will accept. Nonetheless, at $99.95, it may be just the thing for the individual without adequate hardware.

Speaking of sources of software, Kantronics features a full line of programs along with hardware interfaces. Their original interface is a demodulator and AFSK encoder and sells for $169.95. Their new Interface II features a hotter front end, scope outputs, and a bunch of standard shifts. This new one sells for $269.95. In terms of software, Kantronics offers three programs which run with their own, or other (like the MFJ unit above), hardware. The basic Hamsoft program puts many popular computers on RTTY and CW with a full range of features. It is supplied on a ROM board for the VIC-20 ($49.95), Atari ($49.95), TRS-80C ($59.95), or TI-99/4A ($99.95). A disk version is also available for the Apple for $29.95. An advanced version, Hamtext, is available for the Apple, Commodore 64, and VIC-20. This features disk transmit and save modes, printer outputs, and more and sells for $99.95. Also available is Amtorsoft, one of the first programs to run the new AMTOR mode we discussed last month. Running on the same three systems as Hamtext, it sells for $89.95. Looks like an impressive line.

Okay, here comes the other printed material I mentioned. I am about to make my yearly pitch to subscribe to *73*; those of you who presently subscribe may skip to the next paragraph. Do you know how many articles have been published on RTTY in *73*? More than in any other magazine—even more than all of them combined! Yes, this magazine is ideal for keeping up with new knowledge, and at $19.97 (I don't know why the strange number, either—but then when this magazine was first published it went for 37 cents), a year's subscription remains one of the biggest bargains around.

Yet another computer interface is being offered by Contempory Technology, Inc. Their TMC-18 RTTY/CW interface appears to be a demodulator/AFSK keyer which is supplied with software for the VIC-20 and is supposed to run with other brands of computers with appropriate software. With cable and software, this unit sells for $299.35.

On the self-contained front, DGM Electronics presents its SRT-3000, a RTTY/CW/ASCII terminal. This keyboard-shaped unit features a full TTY line display of 72 characters, buffers, cassette interfacing, and stunt-box features. Its price is listed as $995, with an introductory offer of $795. I don't know how long the "introduction" is going on.

When it comes to AMTOR, AEA takes out an ad of its own to show its new AMT-1 AMTOR terminal. This sleek box will act as a demodulator and modulator for AMTOR RTTY, requiring only a terminal and transceiver. You can use a dumb "glass-TTY" type terminal, computer with terminal software, or even an ASR-33, I guess. At $499.95, this will make quite an impression in the growing AMTOR market.

Speaking of dumb terminals, RCA continues to offer used ASR-33 teleprinters for $300. These are pulled from service, and I have no idea what kind of shape any of them are in, but the price is comparable with most other reputable sources for these printers. This may make the ideal remote terminal for some systems or a low-cost printer for others.

Another TRS-80 interface is advertised by the Royal company. For $199 ($179 in cassette version), this disk program and interface will use an external demodulator to put a TRS-80 Model III or 4 on RTTY/CW/ASCII. Space is provided for stored buffers, split screen, diddle, and other features.

Finally, we come to Microfish, a creative name, which sells a cassette program for the VIC-20 to transmit RTTY in Murray and ASCII for $10.95. I presume an external TU is needed, but the price for the software sure sounds good!

Seven years ago, when I started this column, it was the rare advertiser who mentioned RTTY in an ad, much less took out a full-page spread to promote a product to our market. Times have sure changed! Next month, some more from me and you, here in RTTY Loop.

Companies Mentioned in this Month's Column

Radio Amateur Callbook, Inc.
925 Sherwood Drive, Box 247
Lake Bluff IL 60044

The Ham Shack
808 N. Main Street

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

HAMMING AROUND THE WORLD

Without doubt, amateur radio is a hobby unlike any other. While most pastimes are conducted in solitude or with a few close friends, ham radio is definitely a group activity. In fact, our hobby is one of few activities that just can't be conducted alone.

Unless sending code practice is your sole operating thrill, chances are you have dozens of ham friends. And if you hold a General-class ticket or higher, many of those friends are likely to reside overseas. Like no other hobby, amateur radio opens the door to worldwide communication and understanding. What a pity we so often waste this opportunity on meaningless signal reports and hollow chatter about the weather. Get rid of QSL cards and pass a law against the swapping of temperatures and I think we would have a much better hobby.

This month, FUN! takes a look at hamming around the world. It's time to discover what life is like at the end of that overseas microphone, key, or keyboard.

ELEMENT 1 TRUE-FALSE

	True	False
1) In Japan, a resident alien may obtain an amateur-radio operator's license but not a station license.	____	____
2) If you work a West German station with a "Z" suffix, you are communicating with a German Extra-class licensee.	____	____
3) In New Zealand, Field Day is held in February.	____	____
4) The callsigns LG5FL and SJ9WL both belong to the same station.	____	____
5) Bringing a radio into Greece, without the proper paperwork, can result in a $2500 fine and up to two years imprisonment.	____	____
6) In Hong Kong, a visitor's license costs $100.	____	____
7) Tim Chen BV2B is the only licensed amateur in the People's Republic of China.	____	____
8) Father Moran 9N1MM is the only active amateur in Tibet.	____	____

ELEMENT 2 SCRAMBLED WORDS

Unscramble the names of these countries:

NEWSED	JIIF
NAAPJ	LAPEN
BUCA	YTILA
NACFRE	AAISTRU
AAAILSTRU	LEBZIE

ELEMENT 3 MATCHING

Match the prefix to the correct country.

Column A	Column B
1) VU	A) Benin
2) YI	B) Argentina
3) 7X	C) Latvia
4) LU	D) Honduras
5) HR	E) Bangladesh
6) GW	F) Algeria
7) OX	G) Uzbek
8) UQ2	H) Sweden
9) SU	I) Iraq
10) GU	J) Wales
11) EP	K) Turkey
12) TY	L) India
13) PY	M) Venezuela
14) S2	N) Mexico
15) UI8	O) Brazil
16) TA	P) Egypt
17) 5N	Q) Iran
18) XE	R) Nigeria
19) YK	S) Greenland
20) YV	T) Syria
	U) Guernsey

ELEMENT 4 MATCHING

Column A	Column B
1) *Break-In*	A) Italy
2) *Radio Rivista*	B) United Kingdom
3) *Radio Communication*	C) United States
4) *73: Amateur Radio's Technical Journal*	D) Canada
5) *TCA*	E) New Zealand
	F) Spain

ELEMENT 5 MATCHING

Match the DX net to its frequency.

Column A	Column B
1) Forty-Meter DX Net	A) 7.270 MHz
2) Africana Net	B) 21.345 MHz
3) Arabian Christian Net	C) 21.355 MHz
4) Pacific International DX Net	D) 28.510 MHz
5) W7PHO Family Hour (15-meter version)	E) 21.280 MHz
6) W7PHO Family Hour (20-meter version)	F) 14.305 MHz
7) DX to DX Net	G) 14.225 MHz
8) 10-Meter DX Net	H) 14.265 MHz
9) P29JS DX Net	I) 14.265 MHz
10) Arabian Nights DX Net	J) 14.250 MHz
	K) 7.182 MHz

THE ANSWERS

Element 1:

1—True And he must notify the government before operating any station.

2—False Someone employed by the German Department of Telecommunications.

3—True Well, it's summer down there, I hope.

4—True The station is in a place called Morokullen, located on the border between Sweden and Norway. Morokullen, incidentally, means "fun" in both languages. You read it here first.

5—True Yeah, but those window bars make great radiators.

6—True In Hong Kong dollars, of course. That's $16 U.S.

7—False Only ham in Taiwan. On CW, he's BV2A.

8—False Other side of the mountain—Nepal.

Element 2:

(Reading from left to right): SWEDEN, FIJI, JAPAN, NEPAL, CUBA, ITALY, FRANCE, AUSTRIA, AUSTRALIA, BELIZE.

Element 3:

1 = L, 2 = I, 3 = F, 4 = B, 5 = D, 6 = J, 7 = S, 8 = C, 9 = P, 10 = U, 11 = O, 12 = A, 13 = O, 14 = E, 15 = G, 16 = K, 17 = R, 18 = N, 19 = T, 20 = M.

Element 4:

1 = E, 2 = A, 3 = B, 4 = C, 5 = D.

Element 5:

1 = K, 2 = C, 3 = F, 4 = H or I, 5 = B, 6 = G, 7 = E, 8 = D, 9 = H or I, 10 = J.

SCORING

Element 1:
Two points for each correct answer.
Element 2:
Two points for each country unscrambled.
Element 3:
Two points for each pair matched.
Element 4:
Two points for each pair matched.
Element 5:
Two points for each pair matched.

Are you a ham of the world?

1-20 points—Never traveled more than 25 miles from your QTH.
21-40 points—Once vacationed in Cedar Rapids, Iowa.
41-60 points—Know your way around a map.
61-80 points—A seasoned traveler.
81-100+ points—Home QTH is any DXpedition.

Cedarhurst NY 11516

DR. DIGITAL'S MAILBAG

Before we continue last month's discussion of dealing with sound using microcomputers, I am going to reach into the Dr. Digital mailbag and pass along some info I've received. Let me state once more: If you want a reply to your letter, please enclose a stamped, self-addressed envelope!

James J. Brown N2AXR asked about the 10-Ohm variable resistor in the VIC-20-to-ham-rig interface (September, 1983). Sorry about that, Jim—that was a misprint. It should have been a 1000-Ohm variable resistor. Actually, any small resistance variable pot will do; it serves to control the level so you don't drive the rig too hard.

For those of you who have TI-99/4A computers, you too can have cassette-port QSOs (see September, 1983, for details). Jim Ketcham KA4AFI tells me that his TI cassette port works fine through his 2-meter hand-held. Jim has been able to send and receive TI cassette-port data through his local repeater. He just has to time himself so the repeater doesn't try to identify during a data transmission!

It seems that the 1802 microprocessor still has a loyal following. Bob KC2WZ, WA2EGP, and K2ULR have been experimenting with this unique chip. Bob says that he "would like to see different makes of computers talk to each other." He also reports success transferring CoCo programs using the cassette port, although QRN has led to some transmission errors.

Atari computer owners would probably find the Atari Microcomputer Network useful. The net, organized by Jack McKirgan II WD8BNG, has a number of sections. Organization is as follows: National Net—14.325 at 1600Z, Sunday; Midwest Regional Net—7.235 at 1830Z, Sunday; West Coast Regional Net—7.235 at 11 am PST, Sunday; Southwest Regional Net—7.230 at 1800Z, Sunday; Pacific NW Regional Net—7.230 at 1800Z, Sunday; Southeast Regional Net—7.235 at 1800Z, Sunday; East Coast Regional Net—3.965 at 8 pm EST, Wednesday; International Net—21.4 at 2330Z, alternate Thursdays; Dayton, Ohio, Net—open channel on 146.445 simplex; Chicago Net—open channel on 147.570 simplex; Central Kentucky Net—145.45 repeat, 9 pm Wednesdays.

The Atari Microcomputer Network also puts out a very informative newsletter, *Ad Astra*. For more information on the newsletter or the net, write to Atari Microcomputer Network, Jack McKirgan II, 4749 S.R 207 NE, Washington Court House, Ohio 43160.

Joseph J. Fairclough WB2JKJ is doing something unusual with amateur radio and microcomputers: He's using them to help teach English. Joe has an amateur-radio station and a number of microcomputers set up in his classroom at Junior High School #22 in New York City. The high technology serves to create and maintain interest among the students. Using technical publications such as *73* as textbooks, the students in Joe's English class learn about writing. They compare writing styles, catch errors that the copy editors might have missed, and evaluate various publications. The computer and amateur-radio theme keeps the students interested and eager to learn. Joe's unique approach to teaching English has been very successful—he even received a letter from President Reagan congratulating him on the effectiveness of his curriculum.

SOUND: PART II

Last month, we discussed how to detect and measure sound with a computer. Now it's time to look at the other part of the problem—generating sound with a computer. For the purposes of this discussion, I'll divide computers into three classes: computers with no sound-generation hardware, computers with simple console speakers, and computers with separate sound-generating hardware. An example of the first class would be practically any business micro; the only way these can generate sound is through the terminal's beeper. The second type of computer would be the Apple II, Franklin, IBM PC, etc.; these computers have a speaker that can be controlled with software. Atari and VIC computers fall into the third category. These models incorporate circuitry dedicated to sound production. For example, the POKEY chip in the Atari computer can control up to 4 voices. It has a D/A converter, noise generator, and all sorts of options. The VIC computer works in a similar manner. DTMF

generation can be had with a few lines of simple software!

If you have a computer of the first class, don't despair. All you have to do is add an amplifier to one of the output lines of the parallel ports. (If you don't have a parallel port, then you can despair.) Be sure you put an attenuator between your parallel port and your amplifier—there is ±5 V coming out of the port. After you have this, you can consider your computer to be in the second class and use the software techniques that I will describe.

Apples and their relatives have built-in speakers. The speaker is mapped to a specific memory location. Accessing the location with a READ statement will cause the speaker to change state—the sound cone will move from "in" to "out" or vice versa. Note that on the Apple a WRITE to the speaker's location will cause the speaker to click. This is because a WRITE actually performs a READ before it executes.

Other computers with speakers, and those with an amplifier connected to a port, require an I/O statement to cause the speaker to click. The port's number must be determined (consult your hardware manual) and an assembly-language command, usually an OUT command, must be executed. For example, if you have a Z80-based system and have a speaker hooking you to the LSB (least significant bit) line of parallel port #1, the command OUT 1,A can be used to move the speaker's coil in and out. If there is a 1 in the accumulator, the speaker will move out. A zero brings it back in again.

Now that you have the ability to move a speaker in and out, the next step is generating a tone. To do this correctly, we must use assembly language. BASIC is too slow—only low buzzes can be generated under its control. (Some BASICs have built-in sound commands. These can be used, but they generally don't have too much flexibility.) Compiled languages are faster, but they don't allow direct control of the speaker. One doesn't know how long an instruction takes to execute. With assembly language, however, one can precisely determine timing delays. The program in last month's column demonstrated the cycle counting techniques.

The simplest program to generate sound would be (in a pseudo assembly language):

```
START   LOAD     SPEAKER,1
        CALL   DELAY
        BRANCH   START
```

The DELAY subroutine is time critical. It must produce a delay depending on the value of a register. For increased resolution, a 16-bit register should be used. On a computer with only 8-bit registers, a nested loop of two 8-bit index registers can serve the same function. See Listing 1 for a simple tone routine tor the Apple computer.

```

Listing 1. Simple tone routine for the Apple.

The frequency of the tone generated can be easily computed as follows:

1) Determine the number of clock cycles that the delay routine takes to execute.

2) Add to this the number of cycles for the LOAD, CALL, and BRANCH statements.

3) Take the reciprocal of the computer's clock frequency in Hertz.

4) Multiply this by the total number of clock cycles for the tone routine.

5) Take the reciprocal of this product.

6) Multiply by 2 to get the frequency at which the speaker is oscillating.

Very accurate tone production is possible with this technique. Unfortunately, you are limited to a square wave (see Fig. 1).

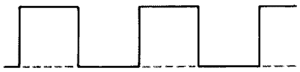

Fig. 1. The square wave.

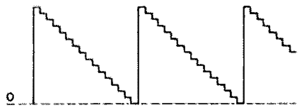

Fig. 2. Sawtooth wave approximated with the Atari POKEY chip.

The tone color of a square wave resembles that of a clarinet. It is not possible to generate complex waveforms, although it is possible to approximate them. As a matter of fact, dual tones and speech can be approximated using a square wave. In a later column, I'll discuss computer-generated speech and elaborate on computer-speech techniques.

Computers with sound hardware offer a great deal more flexibility. The Atari, for example, uses a custom chip. It is possible to have 4 tones with 8-bit resolution and to combine sound generators for higher resolution. Also, 16 amplitude levels are available, making it possible to generate a variety of waveforms (see Fig. 2). The waveforms aren't as pure as an analog wave, but they are reasonable approximations. Producing tones on the Atari is simply a matter of POKEing the correct values into the sound registers. Many things can be done directly from BASIC. Also, as the sound hardware is independent of the microprocessor, the sound can be playing as the program is running. It would be easy to use an Atari for any amateur-radio tone-generation task. SSTV, PL tones, and RTTY tones are three obvious examples.

Anyone experimenting with sound on the Atari computer should get a copy of the Atari *Technical Reference Notes*. This extensive manual gives the complete hardware description of the machine. It is a shame that Atari does not supply this information with the computers—you must buy it separately. I'm sure there are many Atari users out there who don't realize the sophistication of the Atari hardware. The documentation Atari supplies with their computers is useless.

Commodore's VIC and 64K computers have hardware similar to the Atari's. Sound generation is also done in hardware and many Atari programming techniques can be transferred to the Commodore line. VIC owners should have no trouble generating RTTY tones, slow-scan tones, or touch-tones with simple programs.

Next month, I'll have a listing of a DTMF generation program for the Atari. Also, I'll start to discuss computerized speech. I appreciate all the mail I have been receiving and will answer all letters if there is an SASE enclosed

ARRL 160-METER CONTEST
Starts: 2200 GMT December 2
Ends: 1600 GMT December 4

The object is for amateurs worldwide to exchange QSO information with W/VE amateurs on 1.8-MHz CW only. DX-to-DX QSOs are not permitted for contest credit. Operating categories include single operator and multi-operator (single transmitter only). Remember that W/VE stations may transmit only in the segments 1800–1825 and 1830–1850 kHz in conformance with the ARRL band plan. Please refrain from using the 1825–1830-kHz DX window.

EXCHANGE:

RST and ARRL section, DXCC country name, or ITU region (if maritime or aeronautical mobile).

SCORING:

Count 2 points per QSO with amateurs in an ARRL section. W/VE stations count 5 points for DX QSOs. Multiply QSO points by the total number of ARRL sections (74 max) and DXCC countries (W/VE stations only).

ENTRIES:

Official forms and logs are recommended and are available from ARRL headquarters for an SASE or 1 IRC. Logs must indicate time in GMT, call, and exchange. Multipliers should be clearly marked in the log the first time worked. Entries with more than 200 QSOs must include cross-check sheets. Entries must be postmarked by January 4 and addressed to ARRL, Newington CT 06111.

Certificates will be awarded to the top-scoring single operator in each ARRL section and DXCC country and to the top-scoring multi-operator stations in each ARRL division and continent. Usual ARRL conditions of entry and disqualifications apply.

ARRL 10-METER CONTEST
Starts: 0000 GMT December 10
Ends: 2400 GMT December 11

Contact as many stations as possible on the 28-MHz band using no more than 36 hours of the 48-hour contest period. Listening time counts as operating time! Entry categories include: single-operator mixed-mode (phone and CW), phone only, or CW only. Multi-operator class is for single transmitter, mixed-mode only.

No crossmode contacts are allowed. Mixed-mode single-operator and all multi-operator stations may work stations once on CW and once on SSB. One operator may not use more than one callsign from

any given location during the contest period. All entrants may transmit only one signal on the air at any given time.

EXCHANGE:

W/VE stations (including KH6/KL7) send RS(T) and state or province. DX stations send RS(T) and serial number starting with 001. Maritime and aeronautical mobile stations send RS(T) and ITU region (1, 2, 3). Novice and Technician stations sign /N or /T as appropriate.

SCORING:

Count 2 points per phone QSO, 4 points per CW QSO, and 8 points for QSOs with US Novice or Technician stations. Multiply the QSO points by the total number of US states, Canadian call areas, DXCC countries (except US and Canada), and ITU regions (maritime and aeronautical mobiles only).

ENTRIES:

Official logs and entry forms are recommended and are available from ARRL headquarters for an SASE or 2 IRCs. Logs must indicate time in GMT, mode, call, and exchange for each QSO. Multipliers should be clearly marked in the log the first time worked. Entries with more than 500 QSOs must include cross-check sheets. Entries must be postmarked by January 11 and addressed to ARRL, Newington CT 06111.

Certificates will be awarded to: the highest-scoring single-operator station in each category from each ARRL section and DXCC country; top multi-operator entries in each ARRL division and each continent; and additional entries as participation warrants. Usual ARRL entry conditions and disqualifications apply.

3RD ANNUAL 40-METER WORLD SSB CHAMPIONSHIP 0000Z to 2400Z January 7, 1984

SPONSORED BY:

73: Amateur Radio's Technical Journal.

MISCELLANEOUS RULES:

Work as many stations as possible on 40-meter phone during the specified times of allowable operation. The same station may be worked once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are *no less than 30 minutes each.*

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental 48 United States and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contacts with W/VE stations located within the continental 48 United States and Canada. All other contacts score 10 points each. List points for each contact on your log sheet(s).

MULTIPLIERS:

1 multiplier point is earned for each US state, 48 maximum (a District of Columbia contact may be substituted for a Maryland multiplier), each Canadian province or territory (13 maximum), and DX country (excluding the continental US and Canada).

FINAL SCORE:

Total QSO points times total multiplier points equals *claimed score.*

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Send an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1984.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each operator class in each of the continental 48 United States, Canadian provinces and territories, and each DX country represented. A minimum of 100 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or to submit an entry, contact: 40-Meter Contest, Dennis Younker NE6I, 43261 Sixth Street East, Lancaster CA 93535.

BROWARD AMATEUR RADIO BULLETIN

NEWSLETTER OF THE MONTH

"Our immediate goal is to establish a viable, active, and properly trained Amateur Radio Emergency Service (ARES) for Broward County."

Those are the no-nonsense words of Peter Van WE4Q, editor of this month's winning newsletter, the *Broward Amateur Radio Bulletin.* And from the looks of it, Peter has the firepower to back him up—not the least of which is the club newsletter. Active public service is the focus for Broward County's amateurs. It takes the form of civil-defense preparedness, emergency communications, and the more mundane (but equally important) CW and theory classes.

The *Radio Bulletin* provides ample evidence of the Broward County hams' organizational abilities. For starters, the *Bulletin*'s front cover has a table of contents, and each area of interest has its own section. Other sources of information, such as the W5YI report, are cited in the news section.

Finally, the *Bulletin* is good-looking. It is printed in a pleasing combination of light-gold-colored paper and brown ink, giving it a handsome and somewhat formal appearance.

To enter your newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

5TH ANNUAL 160-METER WORLD SSB CHAMPIONSHIP
0000Z January 14, 1984 to 2400Z January 15, 1984

SPONSORED BY:

73: Amateur Radio's Technical Journal.

OBJECT:

To work as many stations as possible on 160-meter phone in a maximum of 32 hours allowable contest time. Multi-operator stations may operate the entire 48-hour contest period. Stations may be worked only once.

ENTRY CATEGORIES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the continental US and Canada transmit RS report and state or province/territory. All others transmit RS report and DX country.

POINTS:

5 QSO points for contact with W/VE stations contacted within the continental 48 United States and Canada. All other contacts earn 10 points each.

MULTIPLIERS:

1 multiplier point will be earned for each of the continental United States, 48 maximum (a District of Columbia contact may be substituted for a Maryland multiplier), each of the Canadian provinces/territories (13 maximum), and each DX country outside the continental 48 United States and Canada.

FINAL SCORE:

Total QSO points times total multiplier points equals *claimed score.*

CONTEST ENTRIES:

Each entry must include log sheets, dupe sheet for 100 or more contacts, a contest summary, and a multiplier check sheet.

ENTRY DEADLINE:

All entries must be postmarked no later than February 19, 1984.

DX WINDOW:

Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by top-band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band. During the contest, all W/VE stations are requested to utilize only those frequencies from 1.808-1.825 and 1.830-1.900 MHz.

DISQUALIFICATIONS:

Disqualification may result if a contestant omits any required entry form, operates in excess of legal power authorized for his/her given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which reduce the overall score more than 2%. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each entry category in each of the continental United States, each Canadian province/territory, and each DX country. A minimum of 100 QSOs must be worked to qualify.

CONTEST ADDRESS:

To obtain information or entry forms (enclose an SASE) or to submit a contest entry, contact: 160-Meter Contest, Harry Arsenault K1PLR, 603 Powell Avenue, Erie PA 16505.

3RD ANNUAL RTTY WORLD CHAMPIONSHIP
0000Z to 2400Z February 25, 1984

SPONSORED BY:

73: Amateur Radio's Technical Journal and *The RTTY Journal.*

OPERATOR CLASSES:

(A) Single operator, single transmitter. (B) Multi-operator, single transmitter.

ENTRY CATEGORIES:

(A) Single band (B) Allband, 10-80 meters.

EXCHANGE:

Stations within the 48 continental United States and Canada must transmit RST and state or province/territory. All others must transmit RST and consecutive contact number.

MISCELLANEOUS RULES:

The same station may be worked once on each band. Crossmode contacts do not count. Single-operator stations may work 16 hours maximum, while multi-operator stations may operate the entire 24-hour period. Off times are *no less* than 30 minutes each and must be noted in your log(s).

QSO POINTS:

5 QSO points for contacts with W/VE stations located within the continental United States and Canada. 10 QSO points for all other contacts.

MULTIPLIER POINTS:

1 multiplier point is awarded for each of the 48 continental United States (a District of Columbia contact may be substituted for a Maryland multiplier), Canadian provinces/territories, and DX countries worked on each band (excluding US and Canada).

FINAL POINTS:

Total QSO points times total multipliers equals *claimed score.*

CONTEST ENTRIES:

Entries must include a *separate* log for each band, a dupe sheet, a summary sheet, a multiplier checklist, and a list of equipment used. Contestants are asked to send an SASE to the contest address for official forms.

ENTRY DEADLINE:

All entries must be postmarked no later than April 15, 1984.

DISQUALIFICATIONS:

Omission of the required entry forms, operating in excess of legal power, manipulating scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces/territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 25 QSOs must be worked to be eligible for awards.

CONTEST ADDRESS:

RTTY World Championship, c/o *The RTTY Journal*, PO Box RY, Cardiff CA 92007.

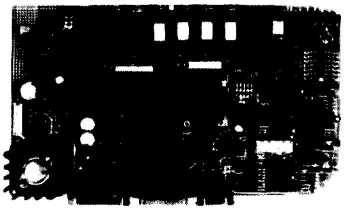
TUCSON AMATEUR PACKET RADIO

Complete Pocket Radio Controller Kit!



- Simple hookup and commands for the newcomer to packet!
- On-board modem designed for optimum performance with standard, unmodified transceivers.
- Retains over 60 user adjustable parameters (including call sign, terminal characteristics, etc.)—even with power removed!
- Full AX.25 and VADCG protocols—built in!
- Simultaneous operation as packet station and digital repeater—built in!
- Full duplex operation (perfect for Oscar 10)—built in!
- RS-232C (to 19.2 kbaud) and Parallel Interfaces—built in!
- Parallel port optionally configurable for link status monitoring—built in!
- 32K ROM and 8K RAM—included! (expandable to 64K without modification)
- On board frequency calibration circuitry for modem—built in!
- Regulated power supply—built in!
- PC board electronically tested to assure quality!

- 200+ page manual with 50 page, heavily illustrated construction section—included!
- Hundreds of TAPR TNCs are in the field NOW!
- For background, see **Ham Radio** (July and August, 1983) and **73 Magazine** (September and October, 1983).
- Support through **PSR**, TAPR's bi-monthly newsletter serving a membership of over 500 amateurs worldwide!
- Introductory price $240 (plus $7 S&H) in the US and Canada (Arizona residents add 5% tax.)
- Manual available separately for $18 (plus $2 S&H) in the US and Canada (manual price creditable towards kit purchase).

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

scriptions (surface mail) is $25 each.

Yes, I'm taking a beating at that rate, but I look at the bright side of it. With the apathy in amateur radio today, how many bucks can I lose? Maybe a dozen of you will probably have any feeling for how happy such a gift would make a foreign ham—particularly one behind the Iron Curtain where they can't subscribe even if they want to because they have Funny Money. I'm not worried.

GETTING INTO THE HAM BUSINESS

Just imagine if your ham shack was a business instead of a personal expense! Well, if you are one of the handful of people who managed to learn to both read and write in school, this blissful state might be achievable.

I got into the ham "business" some thirty years ago when my enthusiasm for amateur radioteletype got so out of hand that I started a monthly newsletter on the subject. This initially philanthropic effort quickly became commercial as the demand for the newsletter grew from the 400 I had envisioned to over 2,000. Philanthropy is fine—in moderation.

Suddenly I was in the newsletter business as a sideline, putting out a monthly publication. That meant I had to have an office in my home to type up the material, draft the diagrams, and take the photographs. It also meant that I could expense my ham purchases, now part of a part-time profitable business.

There are a number of ways to get into the ham business today, with the retailing of ham gear probably one of the very worst. Better to think in terms of writing articles for ham magazines such as this one. It was my RTTY column in *CQ* which leveraged me into the editor's chair there. And that paved the way for me to start *73* five years later.

What to write about? Good heavens! We need articles to encourage amateurs to get involved with new facets of the hobby. RTTY is still, even after all these years, in its infancy. There are dozens—no, hundreds—of needed RTTY articles. OSCAR is extremely underwritten. And the most desperately needed area of all for articles is ham clubs.

Clubs are the strength and the backbone of amateur radio. It's up to our clubs to get youngsters interested in the hobby. It's up to the clubs to have classes to train and license 'em. Clubs should have a wide range of activities to build up ham enthusiasm for the members. Meetings must be fun, even if they include some code practice, a theory discussion, a speaker, and a minimum of club business.

If every club meeting started with a short code-copying test at 10, 20, and 30 wpm, with a prize for the winners in each category, code might turn into being fun. Some members might even do a bit of practicing between meetings in order to get an edge.

DXers should have a chance to infect others with their particularly virulent sickness. Ditto contesters, certificate hunters, and all the other fanatics we breed. Club meetings are the best time to both enjoy and nurture these peculiarities.

There are so many exciting things going on in amateur radio that a writer should be able to turn out one or two articles a month. Some experienced writers look for amateurs who have built a small construction project. Obviously an article should be written, but more often than not, the builder is too busy, so he needs the help of a "professional."

Another area for making money in the hobby is the development of some small product or service which can be sold via mail order. Indeed, many of the larger firms in the ham business got started that way. Electrovoice got started in a garage. Apple, too, started in a garage. My publishing business started in a bedroom in Brooklyn.

Christmas has all sorts of possibilities. It's too late this year, but maybe if you get started planning some special ham Christmas cards or ham jewelry, you'll be ready for 1984.

All is not croissants with running a business in the home. Indeed, you can easily run up against the government bureaucracy with this. It seems that many cities have rather restrictive rules covering businesses in the home. A recent case in Chicago hit the papers when the city declared it illegal for people to use a personal computer in the home for business. And that would include writing articles for pay. If you have such a law in your town, perhaps it's time to get it changed.

Between amateur radio, security systems, and small computers, amateurs couldn't ask for better opportunities to get into small businesses.

POVERTY-STRICKEN HAMS

Now and then I get a letter from a reader whimpering about the price of a subscription or moaning about the high cost of ham gear these days.

As I read *Time* recently, I came across a big article on the bonanza in home protection. Ha! On at least two occasions I have editorialized at length on the opportunities for hams to get into this business. It's a natural for getting started in one's spare time and doesn't take much more than the average ham smarts.

Maybe a dozen hams have grabbed my lapels at hamfests to tell me that they took me seriously on this idea and have, as a result, done very well. Some of them have built up large businesses with dozens of employees—salesmen, installers, and so on.

It's an easy business to get into because there are several firms serving it with mail-order catalogs of the devices and information you need. Of course the business is getting ever more sophisticated, with radio alarms, slow-scan surveillance systems, and so on. That makes it a lot more fun than just putting in some switches, wires, and a big bell.

But the ham who wants to get into some sort of entrepreneurial business can find a wide variety of them where a knowledge of electricity and radio are a help. Some hams have set up television repair benches in their homes and make a very nice piece of change. It's a good cash business. Not a few have gotten into fixing microcomputers, and that could certainly develop into a huge business.

Some keep their eyes open for products which might be of particular interest to hams and be sold via mail-order ads in the ham magazines. Mail order is a clean, fun business. You're your own boss (unless it gets too successful) and it takes almost nothing to get started.

The growth of technology is opening more and more small-business opportunities all the time. But you have to keep your eyes and mind open to spot them. If your eyes are on your TV set, with a six pack and a bag of Doritos at hand, you're going to spend much of your life grumbling about not having *enough* money.

Computers are complicated, but if you passed your ham license honestly, you're halfway along toward understanding them. There are so many opportunities in the micro field that it is shameful. For instance, maybe you don't know it, but there are, even at this late date, virtually no manufacturer's reps in this field. That's right, there are over 450 manufacturers of microcomputers, all desperate for reps, and absolutely none are available. That's a need for over 6,000 reps right off the top.

What does a rep do? A rep acts as an area salesperson for a manufacturer. He goes to the factory for training on the product and its sales. Then it means getting his butt into every store selling computers in his area—which could be fairly large, if he can handle it.

Does it pay? Well, I have known a lot of reps and most of them used to drive Cadillacs. Now they're more into BMWs and Mercedes. You bet it pays. 10 percent is the norm. Heck, if you only have around twenty stores you cover and each sells only one of your computers a week, figuring the wholesale price around $2,500, that brings you a tidy $21,650 a month. Golly, that would even cover your gas costs, eh? A real hustler can obviously do a lot better than

that if the product is good and the factory support is first rate.

Maybe you aren't looking for the big bucks. Okay, in addition to those 450 micro manufacturers, there are another 2,000 manufacturers of support products—accessories, software, and information. Every one of these is an opportunity. Of course most reps take on a bunch of small non-competing products as well as a major. After all, once you're in the store, the hard part is over. And one good seller will make it a lot easier to write orders for other products.

Another nice home business is gathering information and putting it on a computer as a data base. We are coming to a time when we are going to be able to find just about any information we want via the telephone and a computer. I may want to know how many PBX systems there are when I am contemplating a new product. Okay, I'll be able to dial up a service somewhere which will tell me where to find that data, and then I'll dial up the data. I'll be able to get it in seconds.

Now is the time to start researching and entering this data. How many businesses in America have bought office copiers? How many firms are making modems and who are they? Data is increasing in value, so if you pick out some niche of your own and start your data base, you'll eventually have a marketable product.

It's a frame of mind. Everywhere I look I see opportunities for new and profitable businesses. I'm putting together teams to start at least a dozen right now and some of them have the potential for growing into whole industries. Other people can't find anything to do. If I had another 200 hours a week available, it wouldn't be enough.

Even so, I still get on the air an hour or so a week. That short schedule doesn't give me the time it takes to do an effective job of DX-hunting, but then what a silly way to waste a lifetime! I get my share of DX, but mostly I just sit and chat, often finding some extremely interesting people to talk with. Like the chap who designs fountains. Now it really never occurred to me that there were people who spent their professional lives designing fountains. There are, and one's a ham.

Of course you have to ask about a little more than what rig your contact is using—with all due respect to the manufacturers, who the hell cares? Or wonder about the weather, which most of us have all the time. What's he do? What's he interested in? There's where things could get interesting.

Getting back to making money, it's only your not taking the trouble to think about it and do something which is in the way. It's out there—lots of it. And on almost any pretext, people will thrust it at you.

The people who really have it made when it comes to making extra income are the retired! They have time and a half on their hands and a lifetime of experience available. There are probably dozens of firms around which would be interested in getting work done at home on a contract basis.

The retiree who was in advertising can get any quantity of work he can handle. If the person has learned to write, there are needs for writing about nearby interesting people, activities, and so on. Radio stations need part-time writers. Newspapers ditto. Companies need spec sheets, promotions, and so on. It's endless. Few of us manage to get through a lifetime of work without developing some marketable skills. So market them.

Now and then I hear someone complaining that there are no openings in his area. Balderdash! If you have a skill that a firm needs, you make the opening, you don't wait for it. Oh, this takes a bit of research to find some of the weaknesses of the desired firm that you might be able to help with. But if you come to them and point out the reasons why they can't afford not to hire you, no opening is needed.

There are certain skills which are of lifelong value. Salesmanship is one, and it's not that difficult to learn. My firm needs maybe 50 more salespersons. We've been scouring the woods of New Hampshire for months looking for non-smoking salespeople. Bookkeeping is another road to the gold.

No painter, electrician, plumber, carpenter, or so on will ever be short of work in this part of the country. The paint peels off the houses as fast as you put it on. The pipes freeze every winter. The wiring gets gnawed by mice. And zillions of shelves, new porches, repairs to clapboard, and so forth are needed. The retiree with skills can get work any time.

So let's stop with this nonsense about ham gear being expensive. Baloney, it's a fantastic bargain compared to fifty years ago—even twenty years ago. And magazine subscriptions are a steal. Lookie here, your damned five-cent ice cream cones of a few years ago are a buck now. Your lousy 37-cent cover price magazine should, by the same token, be around $7.40 instead of a crummy $2.495. Stop whining.

Subscriptions that were $3 back then should be around $60 now and they're a miserly $19.97, so what's the beef? And you get a whole lot more magazine for your money to boot.

A LOOK AT PIRATES

Bootleggers, as we used to call them in the early days of amateur radio—pirates today, or "Slim" as some DXers log 'em in—have been with us since the very beginning. In fact, those of you who have been reading *73* for a while will remember that the first transatlantic ham contact was made by a pirate! That's right, we've never found out who made that first big one!

Now that it's so incredibly simple to get a Novice license, we don't have the number of beginner ham pirates we used to. The first ticket used to be about equivalent to our Advanced-class license, a fact which encouraged newcomers to get their code practice on the air. Remember too that about 90 percent of all ham contacts in those days were on CW.

That heavy percentage of CW contacts may help to explain to some newcomers (those of you licensed after WWII) why so many old-time hams are so bound up with the importance of The Code. It really was, at one time, important, and old ideas die hard.

My own stratagem, back in 1938, was to pick a call which likely had been issued but which had not yet come out in the *Callbook*. Yep, the *Callbook* was around then, too. There was all the fun of making contacts and talking with people, with the only serious loss being the QSL card. I hung out on 40m, along with about 75 percent of all hamdom. That was the big band in those days. Of course, that was before foreign broadcasting moved in. And it was before the phone ops rose up against the ARRL, formed the National Amateur Radio Council, and got the FCC to okay a 40m ham phone band over the battered body of the ARRL, which really took a beating at the time.

Nope, 40m was a CW band, pure and simple. Everyone, and I mean everyone, was crystal-controlled, since this was before the Invention of the vfo. It was different from today and it was certainly fun. But we can't bring back the old days, we can just remember them.

During the heat of the CB craze when more and more of them were buying sideband rigs and slipping up above the legal channels, there was hysteria in the ham ranks that these turkeys would move into 10m and take over. I tried to reason with these Chicken Littles, but the League was sending their HQ professionals to hamfests preaching panic. The feared invasion never came off, of course.

The CB magazines could have raised hell with us if they had let their readers know the real situation. The fact is that amateur radio has virtually no defense against pirates these days.

In ye olden days, there was the terror of the Radio Inspector. That was followed after 1932 and the formation of the FCC by the fear that an FCC van would pull up in front of your home and an inspector would demand entrance, arrest you, and confiscate your equipment. This did, on rare occasions, happen, so it wasn't a totally unfounded fear.

The situation today is completely different. Sure, we still have laws requiring licenses to operate, but we have an FCC which has been slowly emasculated by laws protecting the guilty and a decreasing amount of money with which to work.

The ham bands are the best policed of any radio service as a result of our own self-policing. Thus the few FCC monitoring stations left seldom bother to even tune a ham band, much less sit there taking bearings on potential pirates and trying to track 'em down. Sending pink slips to erring hams doesn't make money, so it doesn't happen much.

A pirate really has to cause a lot of trouble before the FCC can get any action. Of course if the person has gotten a CB license,

then he's meat for the FCC grinder if he ventures onto the ham bands and actually gets caught red-handed.

About the only thing we have going for us to keep the pirates off our bands is their ignorance. Anyone with a good knowledge of amateur operating could make contacts for years, working DX, working through repeaters, and so on. Who's to know except a QSL bureau somewhere?

Of course getting certificates might present some problems, but then there are obviously going to have to be some sacrifices made by people wanting to avoid even the Bash instant memory system of getting a ham license.

Successful pirates have to change calls periodically, be evasive when talking about personal matters, and not be too blatant about their antennas. Local hams might eventually get curious if a 100-foot tower with a four-element 20m full-sized beam is swinging around their neighborhood.

Other than by a gross unfamiliarity with operating, there is virtually no way to spot 2m mobile pirates. There are so many operators there without even a vague understanding of theory, so a profound ignorance of electronics would never be discovered.

Then we get to the never-never land of marine operating. Once away from land and out of the fiendish clutches of the FCC, who is going to say boo about using the ham bands? This is why such a high percentage of the marine ham stations are pirates. The ITU, from whence all this stems, has no real laws, no police, no monitoring, and very little influence.

Then there are hundreds of religious groups in smaller countries who use the ham bands to keep in touch with each other. Many have even been issued ham calls. These are legal pirates, sort of.

I haven't even hinted at the fun that many licensed hams have by using bogus DX calls. I watched a K2 one time sign a very badly needed DX call in order to see if his rig was working out. It was and the pileup lasted for two hours just from his one CQ while he sat back and guffawed.

There are some hams who point out that if it weren't for an occasional lark like this, the DX chasers would go stir crazy. They need an occasional panic like that to keep fit. And remember the old DX-chaser adage —take no chances; if it sounds like a pirate, work it as fast as you can, just in case it isn't. Work 'em first and ask questions later.

Which brings to mind the antics of several of our more revered DXpeditioners. Like the chap who sat in a hotel in Casablanca and signed the calls of several very rare nearby African countries, making everyone happy. His cards counted for those countries, naturally. Once he paved the way, another DXer did the same thing from Mauritania, and I have his cards from a half dozen countries to prove it.

Those adventures brought on Mr. Big of DXpeditions. I don't know that he was ever at any time in the country he claimed, and I do know of one operation where he was 12,000 miles from where he said. And, yes, most of his QSL cards count for ARRL awards. Now that's pirating on a grand scale. This chap bragged that he was making over $50,000 tax free a year just from DXer donations and I have no reason to disbelieve him.

The drug business in Colombia and other South American countries has leaned heavily on amateur radio. The equipment is cheap. It's available with no questions asked in any quantities. The ham bands are, for the most part, fairly quiet outside of the US and Japan. And 2m—my, oh, my, a wasteland in many areas of the world. So these chaps buy HTs in large numbers, repeaters, the works.

Of course, I can understand the dealer's problem. How can he tell that it isn't a ham buying the equipment? The fact that the chap knows nothing about what he is buying is certainly no clue, right? But when he pulls out a six-inch roll of hundred dollar bills to buy 25 HTs and a repeater, one might expect some hint of question to arise. It should get even more curious when the chap doesn't demand a 20 percent discount but is satisfied to pay the retail price. There was a ham who did that once, but he died.

Are we okay on pirates now?

TET ANTENNA SYSTEMS

"THE PERFECT MATE FOR YOUR SOLID-STATE"

FEATURES

● Dual-Drive For Total Broadband ● Machined Aluminum Boom-To-Mast And Element Mounts ● Lightweight Yet Rugged ● Excellent Gain & F/B Balun (Non Ferrite) Included ● All Elements Active ● Stainless Steel Electrical Hardware Included ● Air Dielectric Coaxial Trap Capacitors ● Precision Machined Aluminum Alloy ● Easy One Afternoon Assembly ● Lower Wind Load ● U.P.S. Shippable

AKIHABARA—PARADISE IN JAPAN

Any ham who has been to Tokyo knows about it—and probably will never forget it. Wives hate it. Anyone suffering from claustrophobia wouldn't want to go near it. But hams, and even a lot of non-hams (poor unfortunates, they are), love it and don't ever want to leave it after they get there.

What is it? It's Akihabara, pronounced "awe-key-ha-bar-a," a district of Tokyo in the northeast corner of Chiyoda ward, only 15 minutes by taxi from the center of the city. Akihabara is the electronics center of Japan, and probably of the world. It has to be seen to be believed.

There are more than 500 retail electronics shops here, offering everything currently on the electric and electronics market, including televison receivers, video recorders, tape recorders, computers, home appliances, stereo equipment, *ad infinitum*, and, of course, ham gear and parts of every description imaginable. Lots and lots of parts. It is truly mind-boggling. Even if you are not a builder, you will wish you were and maybe then and there will decide to become one.

Little stalls underneath the train tracks specialize: Several sell only knobs, another only wire, or transistors, or resistors, or transformers; one shop sells only pilot lights; another sells only aluminum chassis, boxes, and sheet aluminum. And as you walk along, you begin to notice shops that are clones of those you saw moments ago. If you couldn't find the right microphone you wanted at one shop, you can try another, and another. Is it any wonder that wives hate it? Of course, if your wife is also a ham, you'll both be broke before the day is over!

Saturdays and Sundays are the busiest days in Akihabara. Some stores close on Mondays, Wednesdays, or Thursdays.

Before the war, Akihabara was the bicycle center of Tokyo, but when the great war machine was switched on, materials became scarce and bicycle production was discontinued. After the war, a black market initially took over the district. The area did so well that electronics shops scattered around the city took note and decided to move in to take avantage of the big crowds milling around the district. That's when Akihabara began to take shape. As the economy improved, the black-market business began to fade somewhat while the electronics shops began to flourish. One by one they came, and they now dominate the area.

Daily, about 100,000 people shop here, including about 1,000 "foreigners." Many of the shops open at 10:00 am and close at 7:00 pm, so it's good to get an early start. Ham shops are not hard to locate. All you have to do is look up on the roofs for ham antenna arrays (some are magnificent!) and you've got it. Some of the stores will offer as much as 20% off list prices, but there are a few points to be careful about. First of all, the major manufacturers of ham equipment try to protect their dealers overseas. They would prefer that you buy equipment in your own country. If you buy it here, thus saving on shipping costs, the warranty may not be valid back home. Also, you'll play hell trying to get a manual in English. And the voltage here in Japan is 100, so you had better be sure that there is a 110-volt tap on the transformer. Most shops are reluctant to connect the 110-volt tap for you, so you may have to do it yourself when you get home.

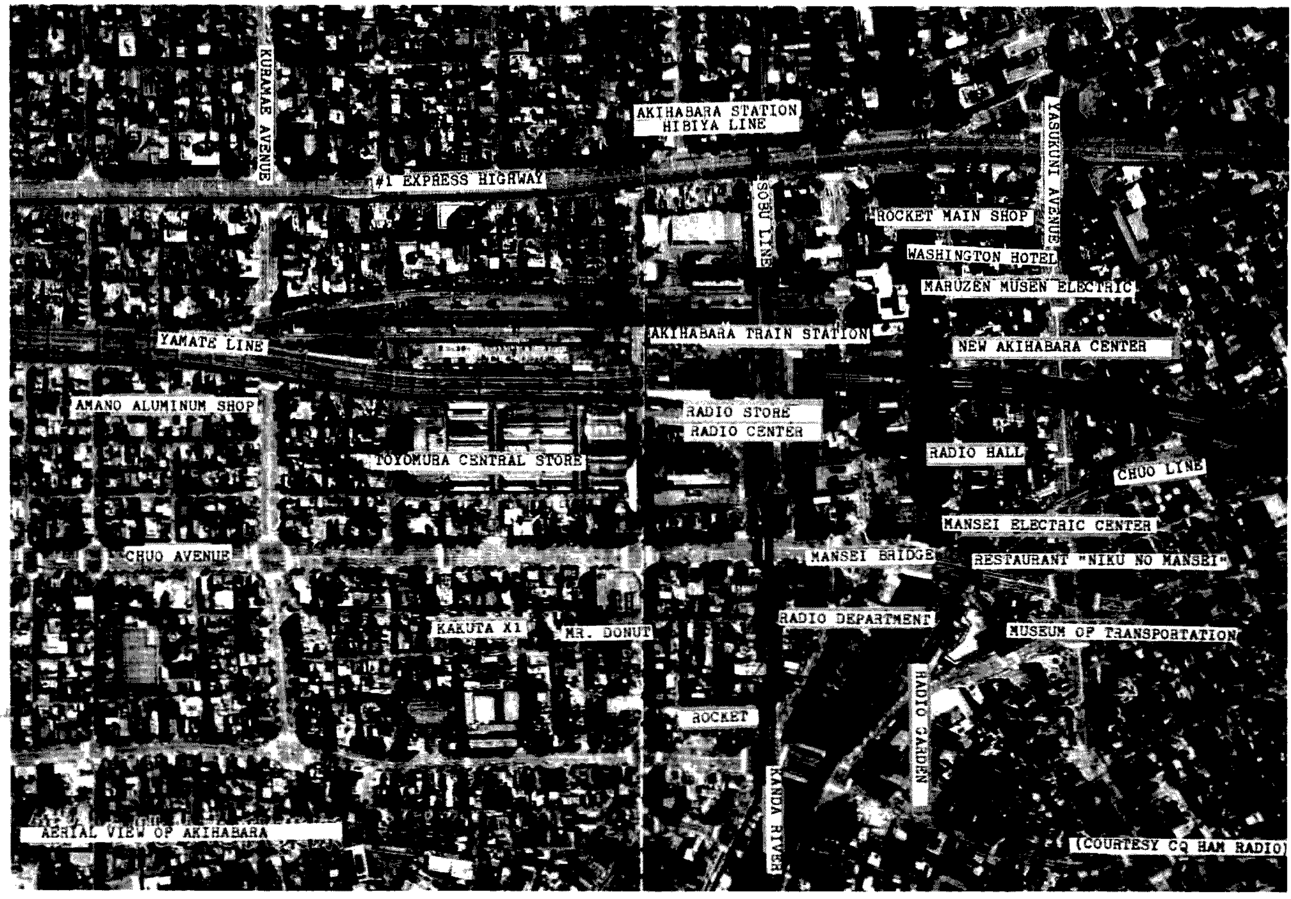
There are other pitfalls, too. The 2-meter rigs sold for use in Japan cover only 144 and 145 MHz. They are capable of operating on the full band, but you may have to make the modification yourself.

A further complicating problem is that most Japanese are not good in English, even though they will try hard to understand you. If anything really complicated comes up, you may come face to face with one of the most baffling language barriers you've ever encountered. If you can arrange it, it is best to visit Akihabara with a Japanese ham friend who speaks English or a professional interpreter, if you can afford it.

Not to be overlooked in Akihabara are the stores dealing in other electrical goods such as TVs, stereos, etc. For this purpose you will see signs displaying "Tax Free Shop," and those shops always have English-speaking people. Here you will find export models for almost everything (except ham gear). Some items will be cheaper than if purchased at "ordinary" shops, as you will be exempt from taxes. Japan does not have sales taxes as we do, but there are certain taxes that are built into the prices of certain items.

Be sure to carry your passport, since you will need it to prove that you are entitled to the tax exemption. Another reason, besides somewhat lower prices, for shopping at the tax-free shops is that they are familiar with the correct voltages and frequencies of each country. For instance, the Japanese FM broadcast band is from 76 through 90 MHz, so if you bought an FM radio in a store not selling export models, you would be stuck with a problem when you tried to use it in the US. There also are problems related to cycles, as half of Japan is on 50 cycles and the other half on 60.

If the sole purpose of your trip to Japan is to immerse yourself totally in electronics, then I would suggest you check into the Washington Hotel, right smack in the middle of Akihabara. No, George Washington hasn't slept here, but if he



Aerial view of Akihabara. (Courtesy of CQ Ham Radio)

Akihabara specialty stores. (Courtesy of CQ Ham Radio*)*

had, he wouldn't have been disappointed. It is not a large hotel, but it is brand spanking new and sparkles inside. Among the conveniences of this hotel you will find a steak house and a coffee shop that serves excellent French pastries.

Apart from the Washington Hotel, there is also a restaurant called Niku-no-Mansei right at the edge of Akihabara, serving delicious steaks, hamburgers, and sukiyaki, and the prices are right! Shopping can be tiring, especially in a crowded city like Tokyo, so you will welcome a place to relax for awhile. Another place worth knowing about is Mister Donut, a branch of the US chain right in the middle of Akihabara, where you can get a cup of coffee and a donut, making your choice from over 30 different varieties. Your feet, not to mention your stomach, will be glad you came.

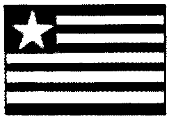
Back to ham-radio stores. There were about 20 at last count, but that number contracts and expands as conditions dictate. Some of the names to remember are Tomihisa, Rocket, Toyomura, and Tsukumo. Some have an occasional English-speaking clerk. For instance, at the moment, Rocket Radio has a Mr. Suzuki who can manage in English quite well. And, incidentally, Toyomura is the only store that deals solely in ham-radio equipment. All the others have branches dealing in electrical applicances, with ham radio only an afterthought.

I won't bore you here with all the details of traveling within Tokyo to get to Akihabara except to say that Akihabara is well served by trains and subways. The center of Akihabara is actually a large train station serving several lines. The subway lines are the Hibiya line and the Ginza line. Best bet is to get one of those subway and train maps that are provided free of charge at the front desk of your hotel. And you can always take a taxi, which would run not more than the yen equivalent of $5 from almost anywhere in Tokyo.

One point which should be made here is that if you do purchase a tax-free item at one of the tax-free stores, the shop clerk will put something in your passport to indicate such. Upon departing Japan, you will be required to show the merchandise that you bought as evidence that you haven't sold it at a profit. Therefore, do not pack your purchases in your luggage. Have them in your hand. Otherwise, you could be slapped with an unpleasant tax.

If you would like current information on stores, locations, and phone numbers, a good idea would be to call the Tokyo International Amateur Radio Association (TIARA) for current information. Call 947-8221 and ask for Yutaka Kasahara (JA1CLN) in the daytime, or at night call 585-2236 and ask for Joe Speroni (AHØA).

Have fun.



LIBERIA

Brother Donard Steffes, C.S.C.

Brothers of the Holy Cross
St. Patrick High School
PO Box 1005
Monrovia
Republic of Liberia

The Ministry of Post and Telecommunications and the Ministry of Transportation jointly celebrated World Communications Year with a seminar held at the University of Liberia. The seminar lasted two days. Papers presenting in-depth studies of conditions as they exist in Liberia were read and discussed.

And the amateurs were there.

The amateurs presented a paper discussing the international character of amateur radio and tried to impress the audience with the idea that the development of amateur radio in Liberia would be advantageous to the nation in many ways. The paper presented international amateur radio as the greatest self-supporting and free community service in the world.

Two aspects of this activity of service were given as examples. It was pointed out first of all that in time of real disaster, it is the amateurs who come through and set up emergency communications, sometimes within hours. The well-known story of the amateurs at work at the time of the earthquake and resultant tidal wave in Alaska was recalled. Then the story, perhaps better known in Liberia, of the Great Lhasa Fever Epidemic was related.

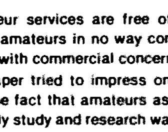
The work of amateurs in time of emergency is so important that other examples really are not needed, but amateurs are not idle when no emergency situation exists. The paper pointed out that in normal day-to-day activity, the amateurs are out there running phone patches for servicemen, furnishing communication for parades, and doing legwork for things like collecting funds for the American Cancer Society. The Red Cross also routinely utilizes the services of amateurs.

It was pointed out that amateur radio is completely noncommercial, and this aspect was developed for the benefit of the audience. The fact was stressed that all amateur services are free of charge and that amateurs in no way compete or interfere with commercial concerns.

The paper tried to impress on the audience the fact that amateurs as a group constantly study and research ways of improving communication. It stated that their record of achievements and contributions in this area are impressive.

Lastly, the friendship developed by amateurs in different countries of the world was mentioned to illustrate the fact that amateur radio promotes understanding between nations. The impact is small, but it is there. The paper made much of the fact that by and large, amateurs are really a great group of people. They are patient, considerate, and polite. They are law-abiding and, to a great extent, monitor themselves. They help each other and others. Any amateur, I think, could recite a long list of instances to illustrate these facts.

Along with the presentation of the paper, an actual amateur-radio station was set up and operated before the whole assembly. Conditions were not the best, but about six contacts were made.



MEXICO

Mark K. Toutjian XE1KMT
Apartado Postal 42-048
06470 Mexico, D.F.

I recently received a letter from Pablo A. Mooser XE1SR, president of the Mexican League of Radio Experimenters (something like the ARRL), congratulating me for the Mexico column in "*73* International." He is the author of various Spanish publications for the League and to the benefit of all Spanish-speaking hams. I was also happy to have received his informative letter with up-to-date information for the Mexico column.

At present, there are 3,240 licensed hams in this country and a total of 65 official radio clubs that are actively promoting interest in ham-related events such as communications experiments by satellite and communications via moonbounce. New licenses are constantly being authorized when individuals pass exams, which include theory, regulations, and Morse code (depending upon the type of license that is solicited). Classes are given for newcomers, dealing with theory and Morse code. It's a special occasion for local clubs to have new licensed members.

During July of this year, the Saltillo (a city in the state of Coahuila) Radio Experimenters Club celebrated its 50th anniversary. This particular radio club is considered the senior member of the Mexican League since it was the first that joined the country's Radio Experimenters League. It was a special occasion for hams nationwide. During the first ceremony of this 50th national meeting of ham-radio operators, the Aztec Diploma was awarded to Jose Luis Jimenez XE1BBF for his outstanding peformance within Mexican ham-radio operations during the past 25 years. Furthermore, the Golden Aztec Award was presented to Fernando Loyola Urquiza XE1FL, Luis Alvarez Urquiza XE1YO, and Juan Lobo y Lobo XE1A for having accomplished 50 years as ham-radio operators and in honor of their outstanding performances over the years in their support of Mexican ham radio.

Ham radio got its start in Mexico in 1926. At present, I am accumulating information pertinent to its history, with the aid of President Pablo A. Mooser, who has kindly offered to provide this and other data.

At present, I'm working on improving my own station, XE1MKT. The tower is being built and I'm purchasing the Hy-Gain TH7DX antenna. I use the Kenwood TS-13-0S barefoot. Look for me on 40-10 meters. You can find me usually around 14.307 MHz or 21.375 MHz, Wednesdays and Sundays. I'd be more than happy to answer your questions with regards to visiting Mexico and keep you informed of current events here in Mexico. Maybe with the new antenna, I'll get a better signal to you! *Saludos* from Mexico. *73* and happy DXing!

THE NBTVA

Do you remember the old televisions with mirror drums and Nipkov disks? The NBTVA (Narrow Bandwidth Television Association) is a club with active members who still use and develop the old low-defi-

Pieter Takens PA3BSR.

nition television system and have their own newsletter. They use homemade cameras and homemade monitors. They have also their professional standards, so that recorded pictures can be exchanged and can be transmitted (if allowed by PTT). Let me give you a sample of the capacities of the system.

Here are the NBTV standards: Lines number 32, scanned vertically upwards; picture repetition frequency—12.5 Hz, scanned right to left; line frequency—400 Hz (32 × 12.5); picture format—3 units vertical by 2 units horizontal; sync pulses (line frequency)—about 5% of the line-duration black.

The picture is basically restricted to close-ups, like a moving passport photograph. For long shots, the definition is too low. Many among you will say, what is the use of a system like this when in today's world you can buy full-color cameras and excellent TV sets and monitors!

Remember well that the practical use is very low; the main reason for building an NBTV camera and monitor is the excitement of using old techniques and to get a picture on the screen with only the very simplest and very basic methods.

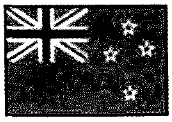
It can easily be explained how the whole thing works. Most of the equipment used at present is based on the Nipkov disk. A Nipkov disk is a thin circular sheet of aluminum with a regular spiral of holes. This disk is rotated on a horizontal axis by a constant-speed motor. In front of the disk there is a lens to focus the image. Behind the disk, there is a photomultiplier or another photosensor. A simple receiver has a similar disk and a motor with accurate speed control and also a modulated light source, replacing the camera's photomultiplier. A large viewing lens replaces the camera lens.

If you're interested in NBTV, the membership of this British/Dutch club is open worldwide. The annual subscription is DFL.11 for Dutch members. Overseas subscription rates on request. Addresses for information: Treasurer: Mr. S. Kujawinski, 54 Park Drive, Hucknall, Nottingham NG15 7IU, United Kingdom; Chairman: Mr. D. B. Pitt, 1 Burnwood Drive, Wollston, Nottingham, United Kingdom; Mr. A. Meyer, 'sGravenpoldersestraat 24, 4433 AH Hoedekenskerke, The Netherlands.

VHF FM ACTIVITY

The photo shows Pieter Takens PA3BSR, who is making a two-way radio contact on the 11th of July on Het Kopje van Bloemendaal, which is said to be the highest dune-top of the Netherlands. It is located near Pieter's QTH and is about 50 meters above sea level. On this spot you have a marvelous view overlooking the city of Haarlem and a part of the North Sea. Amateurs come often from miles around to take advantage of the height of the hill, located about 20 kilometers west of Amsterdam and 5 kilometers from the Dutch coast.

At the time that this photo was taken, Pieter was making a QSO with G6MOP located in Long Sutton, Norfolk (United Kingdom). The hand-held Pieter was using is a converted Storno HT with an output of 350 mW on two meters. The distance covered was 300 km! No wonder hams often go there.



NEW ZEALAND

459 Kennedy Road
Napier
New Zealand

RECIPROCAL LICENSING IN ZL

Countries having reciprocal license agreements with New Zealand are the Netherlands, Sweden, the United States of America, France, and Switzerland. Other countries which New Zealand has amateur-certificate recognition with are Australia, Botswana, Canada, Cook Islands, the Republic of Ireland, Papua New Guinea, Niue, the United Kingdom, and Zimbabwe.

A visitor to ZL-land from any of the above countries may obtain a visitor's license valid for 14 days by presenting a copy of his amateur certificate, his current license, and a receipt for annual fees to any of the Radio Inspector's Offices of the Regional or District Engineer's Offices of the New Zealand Post Office at Whangarei, Auckland, Hamilton, Rotorua, Gisborne, Napier, New Plymouth, Palmerston North, Masterton, Wellington, Nelson, Greymouth, Christchurch, Timaru, Dunedin, and Invercargill.

The visiting amateur will be issued with a ZLØ callsign immediately, provided papers are in order. Each Radio Inspector's Office has its individual allotment of ZLØ callsigns for immediate issue to the 14-day-visitor licensees.

Should the visitor want to stay longer than 14 days, then he must make written application, sending copies of his amateur certificate and current license information so that they are received by the Radio Inspector's Office where he wishes to pick up his visitor's ZLØ call one month before the date the visitor's license is required.

This longer-period ZLØ call for visitors is issued from Post Office Headquarters, Wellington, and is valid for periods of over 14 days and up to one year from the date of issue. The long-term-visitor's ZLØ license is renewable, but after the first year, a normal resident-ZL callsign will be issued in place of the visitor's ZLØ call.

As an example—a visitor using the callsign ZLØXXX/W6 has the prefix of his home call given after the slash following the ZLØ call.

BITS 'N' PIECES

Packet radio (*73*, September, 1983) was used in ZL recently for traffic handling during the recent 24-hour telethon held to raise money for charitable purposes. The Amateur Radio Emergency Corps was asked to provide communication nets for the transmission of pledge messages advising the amounts of money donated, and our regulatory authority, the New Zea-

land Post Office, allowed the NZART AREC to use the occasion as a 24-hour traffic-handling exercise for the amateur emergency nets around the country.

In most areas, VHF/HF traffic nets were used, but at one of the regional telethon centers, Palmerston North, a group of interested amateurs with a mutual interest in packet radio decided to use the Manawatu data repeater to relay the telethon information. Three branches, Dannevirke, Pahiatua, and Hawera, used the system.

The pledge messages were entered in groups of five to ten at a time into the computer, compiled into a standard text form, and sent by datacom (packet radio) via the Manawatu data repeater to a Palmerston North home station, where the demodulated signal was fed into another 6809 computer system, printed out, and delivered to the Central Region Telethon Center. The computers used were Motorola user-group 6809 systems, combining keyboard, computer disk drive, and a user-group modem to couple the VHF transceiver. A local printer was used for the hard copy, although the message files were held on magnetic disk. The whole system was never pushed and could have handled a lot more traffic if it had been available, despite the slow typing speed of most operators.

As luck would have it, the Palmerston North data-station operator lived just over the road from the stadium where the Central Region Telethon Center was located, so the printouts were delivered from time to time by hand.

Participating operators were ZLs 2AYF, 2BNP, and 2TPQ from Dannevirke, ZLs 2TDA, 2TDB, 2TOU, and 2TXC from Woodville, and ZL2TMD, the base station at Palmerston North.

Hamfests, swap and shops, swapfests, flea markets, and swapventions are some of the names of North American activities where amateurs get together and buy or sell their used equipment. They are the source of bargains galore and a place where hams can meet, socialize, and fraternize. Down under in ZL-land, we have another name for these functions, and they operate on a different selling system than on the North American scene. In New Zealand, we call these functions "junk sales"...an occasion where the average ham can clean out the workshop of all surplus equipment, some of it junk, and usually some of it that he purchased at the last junk sale attended. In one or two areas, the junk sales are a little more sophisticated, as they have trading tables and displays of the latest new equipment available by the local representatives of the name overseas manufacturers of amateur equipment. There is also at least one area where a flea market just like those in the US and Canada is organized.

Let's take a closer look at a ZL junk sale.

They are always organized by one of the local branches of NZART (clubs). The branch committee first looks at the year's schedule of junk sales and selects a time which does not clash with another nearby district's sale. Once the date has been set, then an auctioneer must be obtained (and there are one or two good ones within our amateur ranks)—one with sympathetic leanings towards amateur radio. The auctioneer's services are not free of charge, but they cost only an honorary payment.

Next is the venue, a local hall in a central position with plenty of parking space, as amateurs will be coming from as far as 200 miles away. In some very extreme cases, amateurs bitten by the junk-sale bug have been known to travel 500 miles to attend a sale.

Then come the administrative arrangements, the catering arrangements (coffee breaks and lunch), the financial arrangements, and the gathering of the necessary branch members to staff the various departments on the day of the sale. Somewhere between 20 and 30 helpers are needed to run the day properly.

On the day of the junk sale, the various "lots" are presented for recording on the auction forms, and the vendor is given a receipt for his/her surplus equipment (junk). An an average ZL junk sale, there are about three to four hundred lots for auction during the course of a 7- or 8-hour auction period. Selling starts about 9:30 or 10 am and continues nonstop until the lunch break around 12:30 pm. Selling resumes again about 1 pm, continuing nonstop until all the lots have been sold, maybe around 5 pm.

Sales are made on a commission basis, the organizing club getting the commissions charged—usually 15% for their club funds. The range of items for sale covers from *absolute* junk through to near-new transceivers, and in some cases, brand-new components or accessories that have been purchased but never used.

Before the sale starts, the lots are available for inspection up until the time the auction commences, and again at the lunch break, but not during the auction periods.

Besides the auction sale, there are trading tables organized by the club committee, direct-selling small bags of components and/or anything saleable that does not conflict with the auction. Club committees scour the sources of cheap components and then have working bees (collective working parties of members) to bag up the items into saleable quantities. Your correspondent has been counting out 32,000 ½-Watt resistors into 10s and twisting the tails together for what seems like days in preparation for our junk sale to be held soon. My fingers are a bit sore and I'm counting tens in my sleep. The final stage of this working bee will be to bag up the resistors into bags of 32 values, 10 of each value, for sale on the trading table.

On the social side, a junk sale provides the opportunity for a large number of amateurs to congregate together for at least a whole day, and in some cases, where hams travel some distance, possibly overnight, to swap the usual amateur stories of the DX they have worked, etc. Junk sales are great happenings on the ham scene here in ZL; they are occasions when one can empty out the shack or workshop of all that surplus gear you have accumulated over the past year or so and a time when you can go looking for that special piece you need to complete the project you have in mind. It is also one of those times for some amateurs when they bring home more junk than they took to the sale.

ZL junk sales have their regular followers who travel considerable distances to be present and participate in the day's activities, both business and social. From the number on the year's program, they seem to be on the increase in popularity. Each year we see new ones starting up in areas not previously catered to by the sales already operating.

Awards: For certificate hunters, a little bit of advance information on a special award—the City of Hastings Centennial Award—to celebrate the 100th birthday of Hastings, a city of about 50,000 population located in Hawkes Bay, North Island of ZL. The award will be available during the month of February, 1984, all bands, all modes, and those working the required number of stations will receive a handsome colored certificate for their efforts. Details of the requirements will be included in next month's column, in sufficient time for those wishing to participate. Information will also be circulated on most of the overseas nets, but if you miss out, do not hesitate to write to me. Please remember to include 2 IRCs for a reply by aerogramme so that you get the information in time to participate for this special award.

Well, that's about all for this month, as I have to clean out the shack and workshop to get ready for the club junk sale next Saturday. Maybe I'll make enough from my sales to buy that rotary coil I need for the ATU I'm planning. Or maybe I'll be lucky and pick up a whole ATU at a reasonable price. See you all next month.

THE MATCH TOWN AWARD

In 1984, the city of Jonkoping in southern Sweden celebrates its 700-year anniversary. The Swedish chemist Gustav E. Pasch (1788–1862) got a patent in 1844 on his invention of the first safety matches. In 1852, a Swedish manufacturer, John Lundstrom, began to produce them in large quantities in Jonkoping. Between 1916 and 1929, the Swedish export for safety matches was 50 million kilograms annually. Today the Swedish Match Company is a giant international diversified empire that owns factories, forests, mines, and oil wells.

The Match Town Award is a beautiful silk streamer in several colors. You should contact radio amateurs in the Jonkoping community (F6 for the Swedish Commune Award) during the calendar year of 1984. The award is issued by the radio club SVARK, Sodra Vatterbygdens Amatorradioklubb. Every QSO with Jonkoping Commune counts as 1 point. The club station, SK7AX, counts as 2 points. Points required for the award: SM = 4 points, Europeans = 3 points, and DX = 2 points. There is no requirement for QSL cards as proof for contact. The necessary verification can easily be done by the club. Just give the regular QSO data in your application.

Application shall be made to SVARK, PO Box 2035, S-581 02 Huskvarna, Sweden. The fee is either 30 Swedish kroner, 10 IRCs, or US$5.00.

PREFIX OF

Finland has joined the countries that celebrate the 1983 World Communications Year by issuing a special prefix. Between November 18 and December 18, 1983, any Finnish radio amateur can switch the regular OH to the OF prefix.

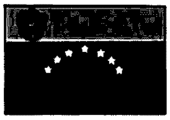
FINNISH *SISU*

The Finns are known for having extraordinary stamina and endurance, called *sisu*. For the 1982 CQ WW DX contest, the club of OH2s, OH2AA, put up a contest effort in order to beat the European record.

The station was OH9W from the Aland Islands, Finnish islands close to Sweden both geographically and linguistically. They have a special status and are a separate DXCC country. On their QSL card, the contest group at OH0W sent a message to all fellow contesters that said:

"We were all born in Finland—a country on the Arctic Circle. It is a country we love, we are even proud of it. We are used to a weather of four seasons—from a swimming July to a freezing February, from a gently awakening April to a reclining October. We are even fortunate enough to have the world's most beautiful archipelago, reaching all the way to the easternmost of the Aland Islands, the OH0. So, why don't we make it from here—be fanatic enough to perfect every bit of action and bring together all the Finns around the fireworks. And win the world from the north of Europe—that's what OH0W was all about. It included 60 potent hams, each given the most suitable assignment, best equipment, massive KLM hardware, all built up in what still is a rare one—OH9. It was crazy all the way through. A storm kept taking down the antennas at the rate we were raising them; the conditions were poor just as the antennas were good and it was like 60 men fighting against the power of Mother Nature. It was kind of fun, however—a once in a lifetime experience—fun you would never repeat. It was 30,000 QSOs in 130 hours and a new European record with a comfortable margin. We are Finns—that's why we go for all this."

The equipment included Yaesu and Drake Twins, Henry and DenTron linears; KLM 6-el Big Stickers and Hy-Gain 5-el monobanders were mounted on seven 100-foot towers made by OH8QD. For the low bands, some highly advanced multiple loops and 1/4-wave verticals laid out straight in the ocean. All in all, the installation required some 3,000 feet of RG-8/L cable. As additional help, they had intercoms, radiotelephones, 25 IC-2E handhelds, and even a helicopter! Maybe this *sisu* makes them always able to beat the Swedes and the other Nordic countries in the Scandinavian Activity Contest as well as the NRAU, Nordic Radio Amateur Union Contest, every year!



VENEZUELA

Luis E. Suarez OA4KO/YV5
PO Box 66994
Caracas 1061-A
Venezuela

During my last trip to California, bought a Lunar GaAsFET preamplifier fo my Kenwood TR-9130. It was intended t be used for satellite work. Back in Cara cas, the preamp was tested and worke like a dream. In fact, it is worth every cen of the US$170 price tag. I have installe this amplifier at several repeater sites i commercial VHF and UHF repeaters an the result is not only more sensitive re ceivers, but less intermodulation, too. I the commercial installations, I used crystal filter ahead to improve selectivity After playing with the jewel, I realized tha it was dangerous to use the preamp in transceiver with no protection against power that would be fed through the inpu You may destroy the GaAsFET in a blink the PTT is accidentally pressed, if only fo a fraction of a second.

I devised a gadget that would disabl the transmitter once the preamp is co nected to the transceiver antenna plu The simplest way I could figure out to do was to place a ring in a PL-259 plug i such a way that, once plugged in, it serve as a lever to actuate a microswitch that u timately will be used to break the PTT lin

The best way to do the task is to break the line going to pin 7 at plug 13 in the drive unit and place a normally-closed micro-switch in between. As the microswitch would be externally installed, the wires connected to it would also be routed outside the radio. I planned to use either of the available auxiliary jacks at the unit rear panel, since I don't like to drill holes in equipment when doing modifications unless there is no other practical way. Should you desire to restore the unit, then it is easy to reverse the procedure, and everything remains as new. Finally, the special PL-259 would be fitted to a short piece of RG-58/U with a BNC male connector at the other end. The BNC connector may then be plugged to the preamp and when you wish to work the satellites, the modified plug would be safely connected to the transceiver and automatically the PTT would be disabled.

That was a planned project and remained like that. Then, yes, it happened. On June 16, I heard OSCAR 10 and hastily plugged in the preamp; the OSCAR 10 beacon came in loud and clear. Two seconds later, the GaAsFET was burned by an accidental touch of the PTT button...

REQUIREMENTS FOR A RECIPROCAL LICENSE

You must request a license from the Ministerio de Transporte y Comunicaciones (form FC-1). The form has 21 boxes to be filled in as follows:

1. Your name and address in your country.
2. In this box you must specify the kind of station you are applying for: AT-F for fixed stations, AT-M for mobile stations, AT-P for portable stations. You must use separate forms for each type of station.
2b. You should specify AFIC (contraction of amateur).
3a. 1 kW.
8a. Base-station address.
8b. City corresponding to above address.
8c. State corresponding to above city.
9a. Make and model of vehicle, if mobile.
9b. Plate or registration number of above vehicle.
9c. "Area del Territorio Nacional."
12. "Instalacion."
18. Your birthplace and date, city, country, nationality, place and date of the application, and signature.
21. In this box you must specify the reason for your application for an amateur license.

Note: Do not fill in boxes 2c, 2d, 4a, 6d, and 7.

You must also include a photocopy of your license and evidence of good standing. A letter stating the reasons for the application is also necessary, along with a photocopy of your passport and visa. You must include a stamp of Bs. 1.00.

The address, if you send the form by mail, is: Ministerio de Transporte y Comunicaciones, Direccion General Sectorial de Comunicaciones, Direccion de Ingenieria, Edificio Centro de Valores, Piso 6 Oficina 6-4, Luneta a Caja de Agua, Caracas 1010, Venezuela. Don't be afraid—addresses are quite long down here in Caracas.

The only problem you may have is that you must apply for the type of station you intend to use: fixed station, mobile station, or portable station. This means that if you intend to operate mobile, you must include vehicle references which may be almost impossible to get if you are going to rent a car. Even when fixed station is your choice, you must know in advance the place where you will be staying. Maybe the portable license is the best choice, in case you carry an HT. If you plan to operate both fixed and mobile, you must apply for both licenses separately.

The best procedure, officially recommended, is to have somebody here, friend or relative, help you with the application. Normally it should take 20 days, but sometimes things go more slowly.

CORRECTIONS

In "Six Antennas from Three Wires," which began on p. 10 of the October, 1983, issue, an incorrect variable was used in the formula for return loss on p. 14. In that formula, "R1" should be "RL."

"New England's Nicad Per-Charger," which appeared in the April, 1983, issue of *73*, contained two errors. In Fig. 1 on p. 39, switch S1A was incorrectly drawn. The common switch lead should be connected to the positive meter line. And in the text, PL2 was mistakenly referred to as J1.

Avery L. Jenkins WB8JLG
73 Staff

FCC

Bowing to pressure from several amateur organizations wishing to rebroadcast the STS-9 shuttle flight, the FCC waived prohibitions against all such transmissions. The Commission added that rebroadcasting would give amateurs experience in space-Earth linking, a skill which may become important in disaster and emergency communications.

The following is a summary of the FCC's decision as it appeared in the *Federal Register*.

Amateur Radio Service Rules; Waiver

AGENCY: Federal Communications Commission.

ACTION: Rule Waiver.

SUMMARY: This document grants a rule waiver to permit retransmission by any licensed amateur radio operator of Space Shuttle audio and video communications on amateur radio frequencies for the exclusive use of licensed amateur radio operators. The waiver is necessary in order to obviate individual waiver requests for each scheduled Space Shuttle flight. By this rule waiver, amateur radio operators will gain experience in establishing *ad hoc* radio links and networks to carry the Space Shuttle information to amateur radio licensees, thereby increasing their technical skills for handling disaster and emergency communication.

DLD AWARDS

The "Deutschland Diplom," DLD

The DLD was introduced by the Deutscher Amateur Radio Club (DARC) on September 1, 1956. It is awarded in two classes, DLD 100 and DLD 200. German and European radio amateurs get the DLD 100 for OSOs on the 80m band only. Radio amateurs of non-European countries get the DLD for OSOs on 80, 20, 15, and 10 meters (mixed). OSOs on 80 meters will be counted twice. Only OSOs since January 1, 1956, are taken into consideration for the DLD.

The "Deutschland Diplom 40-Meter," DLD 40-Meter

The DLD 40-Meter was introduced on May 7, 1959. It is also awarded in two classes, DLD 100/40-Meter and DLD 200/40-Meter. The DLD 40-Meter can be obtained for OSOs on the 40m band. Only OSOs since May 7, 1959, are taken into consideration for the DLD 40-Meter.

Proficiency Badges

The DLD proficiency badges are awarded upon application. The badges will be issued in three classes: *bronze* for DLD 300 (300 confirmed DOKs), *silver* for DLD 400 (400 confirmed DOKs), and *gold* for DLD 500 (500 confirmed DOKs). Note: Blocks of full 100 DOKs per each band must be shown. For example, the bronze badge (DLD 300) may be obtained for any of the following combinations: DLD 100 and DLD 200/40-Meter; DLD 200 and DLD 100/40-meter; DLD 200 and 100 additional confirmed DOKs on 80 meters only; DLD 200/40-Meter and 100 confirmed additional DOKs on 40 meters only. The silver and gold badges are available for analogous combinations.

Stickers

Holders of the DLD 500 may get stickers upon application. These stickers are issued in four classes: *green* for 600 confirmed DOKs, *red* for 700 confirmed DOKs, *silver* for 800 confirmed DOKs, and *gold* for 900 confirmed DOKs. For these classes, the DOKs are summed up regardless of the band (DLD plus DLD 40-Meter).

The "Deutschland Diplom 1000," DLD 1000

Holders of the DLD 500 and any sticker up to 900 may obtain the highest class of the DLD awards, the DLD 1000. Therefore, it is necessary to present the remaining DOKs on 80 and 40 meters (European radio amateurs) or on 80, 40, 20, 15, and/or 10 meters (non-European radio amateurs).

Requirements

DOK means "Distrikts-Ortsverbands-Kenner" (district area indictor). The DOK must be shown in printed form on the OSL cards. Official DARC stamps are admissible for substitution.

There are no restrictions in type or mode of transmitting. The DLD will be awarded if the applicant presents OSL cards with at least 100 different DOKs on a single band only (non-European amateurs on 80, 40, 20, 15, and/or 10).

The fees for DLD awards are as follows: DLD 100, DLD 200, DLD 100/40-Meter, DLD 200/40-Meter, Bronze badge (DLD 300) and DLD 1000—10 DM or 15 IRCs each; Silver badge (DLD 400)—12 DM or 20 IRCs; Gold badge (DLD 500)—15 DM or 25 IRCs; any sticker from 600 up to 900—5 DM or 10 IRCs. The fees should be enclosed with application.

All applications are handled by the "Referat fuer Funkbetrieb" (section for amateur-service operations of DARC). The holders of DLD awards will be published regularly in *cq-DL*, the official club magazine of DARC. Applications accompanied by the original QSLs should be addressed to: H. P. Guenther DL9XW, Am Strampel 22, D-4460 Nordhorn, W. Germany. Note: On request, special applications forms for the DLD awards are available.

The "Deutschland Diplom 10-Meter," DLD 10-Meter

The DLD 10-Meter was inaugurated by the Deutscher Amateur Radio Club (DARC), to liven up the 10m band. Its purpose is to save this band for amateur-radio traffic.

The DLD 10-Meter can be acquired by all radio amateurs holding a license. It will be awarded in the basic class by presenting necessary OSL cards for 50 different DOKs on the 10m band only. Only two-way contacts since January 1, 1976, are taken into consideration. There are no restrictions in the type or mode of transmitting. Endorsement stickers are available for each additional 25 different DOKs worked exclusively on 10-meters.

For the DLD 10-Meter, only those cards which show the DOK in printing can be accepted. Official DARC stamps are admissible for substitution. The fees for the basic award are 10 DM or 15 IRCs; for any additional sticker, the fee is 5 DM or 10 IRCs.

All applications are handled by the "Referat fuer Funkbetrieb" (section for amateur-service operations of DARC). For the handling of the DLD 10-Meter, special application forms are necessary. They can be obtained from DL9XW.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION (Required by 39 U.S.C. 3685). 1. Title of publication, 73 Amateur Radio's Technical Journal. A. Publication no. [illegible] 2. Date of filing, Oct. 1, 1983. 3. Frequency of issue, Monthly. A. No. of issues published annually, 12. B. Annual subscription price, $25.00. 4. Location of known office of publication (Street, City, County, State and ZIP Code) (Not printers), 80 Pine Street, Peterborough, Hillsborough County, N.H. 03458. 5. Location of the headquarters or general business offices of the publishers (Not printers), 80 Pine Street, Peterborough, Hillsborough County, N.H. 03458. 6. Names and complete addresses of publisher, editor and managing editor. Publisher (Name and Address), Wayne Green, 80 Pine Street, Peterborough, N.H. 03458. Editor (Name and Address), Wayne Green, 80 Pine Street, Peterborough, N.H. 03458. Managing Editor (Name and Address), Jack Burnett, 12-C Granite St., Peterborough, N.H. 03458. 7. Owner (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding 1 percent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a partnership or other unincorporated firm, its name and address, as well as that of each individual must be given. If the publication is published by a nonprofit organization, its name and address must be stated.) Name, International Data Group, PO Box 1450, 5 Speen St., Framingham MA 01701. Patrick J. McGovern, PO Box 1450, 5 Speen St., Framingham, MA 01701. 8. Known bondholders, mortgagees and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages or other securities (if there are none, so state) Name, none. 9. For completion by nonprofit organizations authorized to mail at special rates (Section 411.3, DMM only) The purpose, function and nonprofit status of this organization and the exempt status for Federal income tax purposes (check one) Not applicable. 10. Extent and nature of circulation. (X) Average No. copies each issue during preceding 12 months. (Y) Actual No. copies of single issue published nearest to filing date. A. Total No. of copies printed (Net Press Run) (X) 62,532 (Y) 64,594. B. Paid circulation 1. Sales through dealers and carriers, street vendors and counter sales, (X) 11,512 (Y) 17,192. 2. Mail subscriptions (X) 42,162 (Y) 39,839. C. Total paid circulation (Sum of 10B1 and 10B2) (X) 53,674 (Y) 57,031. D. Free distribution by mail, carrier or other means, samples, complimentary, and other free copies (X) 448 (Y) 479. E. Total distribution (Sum of C and D) (X) 54,122 (Y) 57,510. F. Copies not distributed 1. Office use, left over, unaccounted, spoiled after printing (X) 4,347 (Y) 7,084. 2. Returns from news agents (X) 4,063 (Y) 0. G. Total (Sum of E, F1 and 2—should equal net press run shown in A) (X) 62,532 (Y) 64,594. 11. I certify that the statements made by me above are correct and complete.
